OECD GUIDELINE FOR TESTING OF CHEMICALS

Chironomus sp., Acute Immobilisation Test

INTRODUCTION

1. This guideline describes an acute toxicity test to assess effects of chemicals towards chironomids. As a water-only chironomid acute immobilisation assay, it is designed to complement the chronic chironomid OECD test guidelines 218, 219 and 233 (OECD 2004a, 2004b, 2010).

2. The methodology is based on the OECD test guideline 202, the 48-h acute Daphnia sp. test (OECD 2004c). Also, information from existing long-term sediment toxicity test protocols for C. riparius and C. dilutus developed in Europe and North America (Hill et al. 1993; Fleming et al. 1994; USEPA 1996a; USEPA 1996b; Environment Canada 1997; USEPA 2000) and included in previous ring-test experiments (Strelke and Köpp 1995; Milani et al. 1996; USEPA 2000) is taken into account.

PRINCIPLE OF THE TEST

3. First instar Chironomus sp. larvae are exposed to a range of concentrations of the test substance in water-only vessels for a period of 48 hours. Immobilisation is recorded at 24 and 48 hours. The EC₅₀ is calculated at 24 and 48 hours (if data allow).

INFORMATION ON THE TEST SUBSTANCE

4. The water solubility and the vapour pressure of the test substance should be known and a reliable analytical method for the quantification of the substance in the test solutions with reported recovery efficiency, and limit of determination should be available. Useful information includes the structural formula, purity of the substance, stability in water and light, Pₐw and results of a test for ready biodegradability.

Note: Guidance for testing substances with physical chemical properties that make them difficult to test is provided in a separate document (OECD 2000).
REFERENCE SUBSTANCES

5. A reference substance may be tested regularly as a means of assuring that the test system and conditions are reliable. Toxicants which have been used in international ring-tests and validation studies are recommended for this purpose. Examples of reference toxicants used successfully with *Chironomus* sp. are: lindane, pentachlorophenol, cadmium chloride and potassium chloride (Fleming et al. 1994; Strelke and Köpp 1995; Environment Canada 1995; Environment Canada 1997; USEPA 2000). Also, 3,5 dichlorophenol has been used as reference substance (Weltje et al. 2010). Test(s) with a reference substance should be conducted as required, for example after introducing new stock organisms into the culture. However, at least one reference test per year should be conducted.

VALIDITY OF THE TEST

6. For a test to be valid, the following performance criteria apply:

- In the control, including the solvent control, if appropriate, not more than 20 percent of the larvae should show immobilisation or other signs of disease or other stress (e.g. discolouration or unusual behaviour, such as trapping at the water surface) at the end of the test.

- The dissolved oxygen concentration at the end of the test should be $\geq 3$ mg/L ($> 60\%$ of the air saturation value) in control and test vessels.

DESCRIPTION OF THE METHOD

Apparatus

7. Test vessels and other apparatus that will come into contact with the test solutions should be made entirely of glass or other chemically inert material. Suitable test vessels are 50 ml Petri dishes (height: 3 cm, inner diameter: 4.7 cm) or 100 ml beakers (height: 7 cm, inner diameter: 4.5 cm) which should be cleaned before each use using standard laboratory procedures. Test vessels should be loosely covered to reduce the loss of water due to evaporation and to avoid the entry of dust into the solutions. Volatile and other test substances which might be difficult to test should be handled according to the recommendations described in the “Guidance document on aquatic toxicity testing of difficult substances and mixtures” (OECD 2000).

8. In addition, some or all of the following equipment will be used: oxygen-meter (with microelectrode or other suitable equipment for measuring dissolved oxygen in low volume samples); pH-meter; equipment for the determination of hardness; adequate apparatus for temperature control, etc. If the dilution water is from a surface or groundwater source, equipment for the determination of the total organic carbon (TOC) concentration and/or equipment for the determination of the chemical oxygen demand (COD) will be necessary.

Test Organisms

9. First instar larvae of *Chironomus riparius* are used in this test, since they are the most sensitive larval stage. Further, this instar is free swimming and therefore not stressed by the absence of sediment. Although *C. riparius* is the preferred species, *C. dilutus* or *C. yoshimatsui* may also be used. Details on culturing methods are available for *C. riparius* (Annex 2), *C. dilutus* (USEPA 2000) and *C. yoshimatsui*.
(Kawai 1986). Test organisms should come from a source (preferably in-house culture) where identity of the test species has been confirmed.

10. The larvae should be derived from a healthy stock (i.e. showing no signs of stress such as high mortality, discoloured animals, etc.) with a known history (breeding method, culture conditions). All organisms used for an individual test should have originated from the same culture. The cultures should be maintained in conditions (light, temperature, and medium) similar to those to be used in the test. If the *Chironomus* sp. culture medium to be used in the test is different from that used for routine *Chironomus* sp. culture, it is good practice to include a pre-test acclimation period by placing egg masses for hatching and maintaining the first instar larvae in test dilution water at test temperature until the start of the exposure.

### Holding and dilution water

11. Natural water (surface or groundwater), reconstituted water or dechlorinated tap water are acceptable as holding and dilution water if *Chironomus* sp. will survive in it during culture, acclimation and testing without showing signs of stress. Any water which conforms to the chemical characteristics of acceptable dilution water as listed in Annex 3 is suitable as a test water. It should be of constant quality during the period of the test. Reconstituted water can be made up by adding specific amounts of reagents of recognised analytical grade to deionised or distilled water. Examples of reconstituted water are given in Annex 2.

12. In case of natural water, the water quality characteristics listed in Annex 3 should be measured at least twice a year or when it is suspected that these characteristics may have changed significantly. Measurements of heavy metals (e.g. Cu, Pb, Zn, Hg, Cd, Ni) should also be made. If dechlorinated tap water is used, chlorine analysis is desirable. If the dilution water is from a natural source, conductivity and total organic carbon (TOC) or chemical oxygen demand (COD) should be measured.

13. To avoid the necessity of adaptation prior to the test, it is recommended that the water used in the test is the same as used for culturing. The dilution water may be aerated prior to use for the test so that the dissolved oxygen concentration has reached saturation.

### Test Solutions

14. Test solutions of the chosen concentrations are usually prepared by dilution of a stock solution. Stock solutions should preferably be prepared by dissolving the test substance directly in the dilution water. As far as possible, the use of solvents or dispersants should be avoided; however, solvents may be required in some cases in order to produce a suitably concentrated and homogeneous stock solution. Guidance for suitable solvents as well as other aspects of handling difficult substances, such as biodegrading-, complexing-, ionising- or multi-component substances and preparations is available (OECD 2000). For active ingredients or other single chemicals (i.e. not preparations), the test substance in the test solutions should not exceed the practical limit of solubility in the dilution water. If solubilising agents are used, the concentration of solvent should be equal in all test concentrations and in the solvent control. In addition, the maximum allowed solvent concentration is 100 µl/l or 100 mg/l, whichever is lowest (OECD 2000).

15. The test should generally be conducted without adjustment of pH. If the pH does not remain in the range 6-9, then a second test should be conducted, adjusting the pH of the stock solution to that of the dilution water before preparing the test solutions. The pH adjustment, preferably with 0.1 M HCl and 0.1 M NaOH, should be made in such a way that the stock solution concentration is not changed to any significant extent and that no chemical reaction, such as precipitation of the test substance, is caused.
Adjustment within the pH range 6-9 may be appropriate for chemicals which show a difference in stability over this range, in order to maintain test concentrations for 48 hours.

**PROCEDURE**

**Preparation of Test Organisms Prior to Exposure**

16. Four to five days before adding 1\textsuperscript{st} instar larvae to the test vessels (test initiation), fresh egg masses (< 24 h) should be taken from the culture and placed in small vessels in culture medium with a small amount of food. Aged medium from the stock culture or freshly prepared medium may be used. Normally, the larvae begin to hatch within a few days after the eggs are laid (2 to 3 days for \textit{C. riparius} at 20°C, and 1 to 4 days for \textit{C. dilutus} at 23°C and for \textit{C. yoshimatsui} at 25°C). First instar larvae should be used in the test. If necessary, the instar of midge larvae can be checked by measuring the head capsule width (USEPA 2000). Figures 1 and 2 show a freshly laid egg mass and an egg mass that has almost completed hatching, respectively.

![Figure 1: A freshly (< 24 h) laid egg mass of \textit{C. riparius} (from Weltje et al. 2010).](image)

![Figure 2: First-instar larvae from an almost completely hatched egg mass of \textit{C. riparius} (from Weltje et al. 2010).](image)

17. Larvae should not be fed during the test. However, feeding prior to exposure (i.e. directly after hatching) is important in order to ensure \( \geq 80\% \) survival of the larvae in the controls at the end of the exposure period. A few droplets of filtrate from finely ground suspension of flaked fish-food (e.g. Tetra-Min or Tetra-Phyll, see also OECD 2004b) in the amount of 0.05-0.5 mg per larva should be sufficient for young larvae. Green algae have also been suggested as a food source (OECD 2004a, 2004b), but care has
to be taken when larvae are added to the test vessels not to “inoculate” the test medium with algae, which may influence test compound availability. As an alternative to flaked fish-food, plant material may be used, for example stinging nettle (Urtica dioica), mulberry (Morus alba), white clover (Trifolium repens) or spinach (Spinacia oleracea). Other plant material (Cerophyl or alpha-cellulose) may also be used. However, as the amounts of food recommended in the literature vary considerably, it is recommended that individual laboratories determine the amount of food required prior to exposure to ensure adequate survival in the test.

Note 1: Fish food extract, which can be prepared by boiling the fish food suspension followed by removal of the larger particles, e.g. by filtration or by discarding the settled fraction, would typically have around 3.7 g TOC/l of which very small amounts would be carried over to the test vessels.

Note 2: Chironomid larvae may get trapped at the water surface and may not be able to move back into the water column. This mostly depends on the physico-chemical properties of the test substance and/or test medium, but can also be related to the cleaning process of the glass vessels. Introduction of the larvae into the test system by releasing them below the water surface is one way to reduce trapping. As this phenomenon may often result in unacceptable studies (i.e. high control mortality) some guidance on ways to reduce this is discussed here. A possible solution is the addition of a tiny amount of a dispersant, e.g. Tween 80 at 2 µl/l, to reduce the surface tension of the medium, although the use of dispersants is not generally advocated. Another way might be to physically keep the individuals from getting to the air/water interface, e.g. by using sealed vessels without airspace or using a mesh to retain organisms below the surface.

Conditions of exposure

Test groups and controls

18. Test vessels should be filled with appropriate volumes of test solutions. Chironomus sp. first instar larvae should be randomly allocated to the test vessels using a blunt pipette. At least 20 animals, preferably divided into four groups of five animals each, should be used for each test concentration and controls. At least 2 ml of test solution should be provided for each animal (i.e. at least a volume of 10 ml for five larvae per test vessel; which should also be sufficient to allow for adequate samples to be taken for analytical determination of the test concentrations).

Test concentrations

19. A range-finding test may be conducted to determine the range of concentrations for the definitive test. For this purpose, the larvae are exposed to a series of widely spaced concentrations of the test substance. At least ten larvae should be exposed divided over two replicates of each test concentration for 48 hours.

20. In the definitive test, at least five test concentrations should be used, with a dilution water control and solvent control (if appropriate). The solvent control contains the solvent in a concentration identical to the level used in treatments. Concentrations should be arranged in a geometric series with a spacing factor preferably not exceeding 2.2. Justification should be provided if fewer than five concentrations or a larger spacing factor is used, e.g. a shallow slope of the concentration-response curve. The highest test concentration should preferably result in 100 per cent immobilisation and the lowest test concentration should preferably give no observable effect. However, these effect levels are secondary to adequately defining the EC₅₀.
Incubation conditions

21. The water temperature should be within the range of 18 to 22°C, and for each individual test it should be constant within ±1°C. A 16-hour light and 8-hour dark cycle is recommended and the light intensity should be between 500 to 1000 lux. Complete darkness is also acceptable, especially for test substances that are unstable in light.

Duration

22. The exposure commences with the addition of larvae to the test solutions and lasts for 48 h.

Observations

23. Each test vessel should be checked for immobilised larvae at 24 and 48 hours after the beginning of the exposure. Those animals that are not able to change their position within 15 seconds after mechanical stimulation, e.g. by subjecting the larvae to a gentle stream of water from a Pasteur pipette or agitation of the test vessel, are considered to be immobilised. Immobility is used as surrogate parameter for lethality, similar to the definition for neonate daphnids in the 48-h acute test guideline (OECD 2004c), since it is difficult to establish mortality in first instar larvae. In addition to immobility, any abnormal behaviour or unusual appearance should be reported. Immobilized larvae observed at 24 hours are not removed from the test vessels so that their immobility may be confirmed at test end.

Analytical Measurements

24. The dissolved oxygen and pH are measured, as a minimum, in the control(s) and in the highest test substance concentration at the beginning and end of the test. The dissolved oxygen concentration in the control(s) should be in compliance with the validity criterion. The oxygen level in control and test vessels should be reported as the air saturation value. The pH should normally not vary by more than 1.5 units over the course of the test. Temperature is usually measured in control vessels and it should be recorded preferably continuously throughout the test or, as a minimum, at the beginning and end of the test.

25. The concentration of the test substance should be measured, as a minimum, in the control(s), the highest and lowest test concentration, but preferably in all treatments, at the beginning and end of the test. It is recommended that results be based on measured concentrations. However, if evidence is available to demonstrate that the concentration of the test substance has been satisfactorily maintained within ±20 per cent of the nominal or measured initial concentration throughout the test, then the results can be based on nominal or measured initial values.

LIMIT TEST

26. A limit test with a single concentration may be performed at 100 mg/L of test substance or up to the practical limit of solubility in the test medium (whichever is lowest) in order to demonstrate that the EC_{50} is greater than this concentration. The limit test should be performed using 20 larvae (preferably divided into four groups of five), with the same number in the control(s). If the percentage of immobilisation is >20% at the end of the test, a full concentration-response study should be conducted. Any observed abnormal behaviour should be recorded.
DATA AND REPORTING

Data

27. Data should be summarised in tabular form, showing for each replicate of each treatment, the number of larvae exposed, and immobilisation at each observation. The percentages immobilised at 24 and 48 h are plotted against test concentrations. Data are analysed by appropriate models (e.g. probit analysis) to determine the concentration-response curves, their slope and the EC_{50} values with 95% confidence limits (Stephan 1977; Finney 1978). The NOEC may be determined by using Fisher’s exact test (Fisher 1922).

28. Where the standard methods of calculating the EC_{50} are not applicable to the data obtained, the highest concentration causing no immobility and the lowest concentration producing 100 percent immobility should be used as an approximation for the EC_{50} (this being considered the geometric mean of these two concentrations).

Test report

29. The test report must include the following:

Test substance:
- physical nature and relevant physical-chemical properties;
- chemical identification data, including purity.

Test species:
- source and species of Chironomus, supplier of source (if known) and the culture conditions used (including source, kind and amount of food, feeding frequency).

Test conditions:
- description of test vessels: type and volume of vessels, volume of solution, number of chironomids per test vessel, number of test vessels (replicates) per concentration;
- methods of preparation of stock and test solutions including the use of any solvent or dispersants, concentrations used;
- details of dilution water: source and water quality characteristics (pH, hardness, alkalinity, conductivity, etc.); composition of reconstituted water if used;
- incubation conditions: temperature, light intensity and periodicity, dissolved oxygen, pH, etc.

Results:
- the number and percentage of chironomid larvae that were immobilised or showed any adverse effects (including abnormal behaviour) in the controls and in each treatment group, at each observation time and a description of the nature of the effects observed;
- results and date of test performed with reference substance, if available;
- the nominal test concentrations and the result of all analyses to determine the concentration of the test substance in the test vessels; the recovery efficiency of the method and the limit of determination should also be reported;
- all physical-chemical measurements of temperature, pH and dissolved oxygen made during the test;
- the EC$_{50}$ at 48 h for immobilisation with confidence intervals and graphs of the fitted model used for their calculation, the slopes of the concentration-response curves and their standard error; statistical procedures used for determination of EC$_{50}$ (these data items for immobilisation at 24 h should also be reported when they were measured).

- explanation for any deviation from the Test Guideline and whether the deviation affected the test results.
**LITERATURE**

In the context of this guideline, the following definitions are used:

EC\textsubscript{50} is the concentration estimated to immobilise 50 per cent of the chironomids within a stated exposure period.

Immobilisation: Those animals that are not able to change their position within 15 seconds after mechanical stimulation, e.g. by subjecting the larvae to a gentle stream of water from a Pasteur pipette or agitation of the test vessel, are considered to be immobilised.
RECOMMENDATIONS FOR CULTURE OF CHIRONOMUS RIPARIUS

1. *Chironomus* larvae may be reared in crystallising dishes or larger containers. Fine quartz sand is spread in a thin layer of about 5 to 10 mm deep over the bottom of the container. Kieselgur (e.g. Merck, Art 8117) has also been shown to be a suitable substrate (a thinner layer of up to a very few mm is sufficient). Suitable water is then added to a depth of several cm. Water levels should be topped up as necessary to replace evaporative loss, and prevent desiccation. Water can be replaced if necessary. Gentle aeration should be provided. The larval rearing vessels should be held in a suitable cage which will prevent escape of the emerging adults. The cage should be sufficiently large to allow swarming of emerged adults, otherwise copulation may not occur (minimum is ca. 30 x 30 x 30 cm).

2. Cages should be held at room temperature or in a constant environment room at 20 ± 2°C with a photo period of 16 hour light (intensity ca. 1000 lux), 8 hours dark. It has been reported that air humidity of less than 60% RH can impede reproduction.

Dilution water

3. Any suitable natural or synthetic water may be used. Well water, dechlorinated tap water and artificial media (e.g. Elendt "M4" or "M7" medium, see below) are commonly used. The water has to be aerated before use. If necessary, the culture water may be renewed by pouring or siphoning the used water from culture vessels carefully without destroying the tubes of larvae.

Feeding larvae

4. *Chironomus* larvae should be fed with a fish flake food (Tetra Min®, Tetra Phyll® or other similar brand of proprietary fish food), at approximately 250 mg per vessel per day. This can be given as a dry ground powder or as a suspension in water: 1.0 g of flake food is added to 20 ml of dilution water and blended to give a homogenous mix. This preparation may be fed at a rate of about 5 ml per vessel per day. (shake before use.) Older larvae may receive more.

5. Feeding is adjusted according to the water quality. If the culture medium becomes ‘cloudy’, the feeding should be reduced. Food additions must be carefully monitored. Too little food will cause emigration of the larvae towards the water column, and too much food will cause increased microbial activity and reduced oxygen concentrations. Both conditions can result in reduced growth rates.

6. Some green algae (e.g. *Scenedesmus subspicatus*, *Chlorella vulgaris*) cells may also be added when new culture vessels are set up.

Feeding emerged adults

7. Some experimenters have suggested that a cotton wool pad soaked in a saturated sucrose solution may serve as a food for emerged adults.
**Emergence**

8. At 20 ± 2°C adults will begin to emerge from the larval rearing vessels after approximately 13 - 15 days. Males are easily distinguished by having plumose antennae and thin body.

**Egg masses**

9. Once adults are present within the breeding cage, all larval rearing vessels should be checked three times weekly for deposition of the gelatinous egg masses. If present, the egg masses should be carefully removed. They should be transferred to a small dish containing a sample of the breeding water. Egg masses are used to start a new culture vessel (e.g. 2 - 4 egg masses / vessel) or are used for toxicity tests.

10. First instar larvae should hatch after 2 - 3 days.

**Set-up of new culture vessels**

11. Once cultures are established it should be possible to set up a fresh larval culture vessel weekly or less frequently depending on testing requirements, removing the older vessels after adult midges have emerged. Using this system a regular supply of adults will be produced with a minimum of management.

**Preparation of test solutions "M4" and "M7"**

12. Elendt (1990) has described the "M4" medium. The "M7" medium is prepared as the "M4" medium except for the substances indicated in Table 1, for which concentrations are four times lower in "M7" than in "M4". The test solution should not be prepared according to Elendt and Bias (1990) for the concentrations of NaSiO$_3$ ⋅ 5H$_2$O, NaNO$_3$, KH$_2$PO$_4$ and K$_2$HPO$_4$ given for the preparation of the stock solutions are not adequate.

**Preparation of the "M7"-medium**

13. Each stock solution (I) is prepared individually and a combined stock solution (II) is prepared from these stock solutions (I) (see Table 1). Fifty ml from the combined stock solution (II) and the amounts of each macro nutrient stock solution which are given in Table 2 are made up to 1 litre of deionised water to prepare the "M7" medium. A vitamin stock solution is prepared by adding three vitamins to deionised water as indicated in Table 3, and 0.1 ml of the combined vitamin stock solution are added to the final "M7" medium shortly before use. The vitamin stock solution is stored frozen in small aliquots. The medium is aerated and stabilised.

* However, it should be noted that if there is an interaction suspected between hardness ions and the test substance, lower hardness water should be used (and thus, Elendt Medium M4 must not be used in this situation).
