

The Social Institutions and Gender Index (SIGI) *

Introduction

Gender inequalities have been on the political agenda for many years (World Bank, 2001). To measure the extent of this problem at the country level many gender-related indices have been proposed, e.g. the Gender-Related Development Index (GDI) and the Gender Empowerment Measure (GEM) (United Nations Development Programme, 1995), the Global Gender Gap Index from the World Economic Forum (Lopez-Claros and Zahidi, 2005), the Gender Equity Index developed by Social Watch (Social Watch, 2005) or the African Gender Status Index proposed by the Economic Commission for Africa (Economic Commission for Africa, 2004). These measures focus on gender inequalities in well-being or in agency and are typically outcome-focused (Klasen, 2006, 2007). The Women Social Rights Index of the CIRI Human Rights Data Project 1 complements these indices as it takes a human rights perspective. It measures whether a number of internationally recognized social rights for women are included in law and whether governments enforce them.

The new OECD Social Institutions and Gender Index (SIGI) adds to these indices another important aspect related to gender inequalities. It measures social institutions that are mirrored by societal practices and legal norms that produce inequalities between women and men. The SIGI is not only an overall measure of these institutions. It is also composed of five subindices, which make disaggregated information available. Each of the five subindices measures a different dimension of social institutions related to gender inequality: Family code, Civil liberties, Physical integrity, Son Preference, and Ownership rights. As the indicators that enter the SIGI primarily measure social institutions that pose problems in the developing world, the SIGI covers only non-OECD countries. 2

The SIGI and its subindices are useful tools to compare the societal situation of women in non-OECD countries as they allow the identification of problematic countries and dimensions of social institutions that deserve attention by policy makers and need to be scrutinized in detail.

The first part of this document introduces the underlying concepts of the SIGI and its five subindices. The following parts present the method of index construction as well as results by country and interesting regional patterns. The last section ends with a discussion.

* Boris Branisa, Stephan Klasen and Maria Ziegler (University of Goettingen)
Denis Drechsler and Johannes Jütting (OECD Development Centre)

1 Information is available on the webpage of the project <http://ciri.binghamton.edu/>.

2 For details on the construction of the SIGI and its subindices, see Branisa, Klasen, and Ziegler (2009).

Measuring Social Institutions related to Gender Inequalities

Instead of measuring gender inequalities in education, health, economic or political participation and other dimensions, the SIGI measures important inputs – social institutions – to such outcome inequalities in non-OECD countries. These social institutions are conceived as long-lasting codes of conduct, norms, traditions, informal and formal laws. Therefore, the index and the five subindices are not meant to reflect fast changes over time.

The five components of the SIGI measure each one dimension of the general underlying concept. These subindices are constructed using variables from the OECD Gender, Institutions and Development Database (Morrison and Jütting, 2005; Jütting, Morrison, Dayton-Johnson, and Drechsler, 2008).³

The *Family code* subindex refers to institutions that influence the decision-making power of women in the household. The following variables are included. *Parental authority* measures whether women have the right to be a legal guardian of a child during marriage, and whether women have custody rights over a child after divorce. *Inheritance* is based on formal inheritance rights of spouses. *Early marriage* measures the percentage of girls between 15 and 19 years of age who are/were ever married. *Polygamy* measures the acceptance of polygamy in the population. Countries where this information is not available are assigned scores based on the legality of polygamy.⁴

The *Civil liberties* subindex captures the freedom of social participation of women and includes the following variables. *Freedom of movement* indicates the freedom of women to move outside the home. *Freedom of dress* is based on the obligation of women to follow a certain dress code, for example to cover parts of their body in the public.

The *Physical integrity* subindex comprises different indicators on violence against women. *Violence against women* indicates the existence of laws against domestic violence, sexual assault or rape, and sexual harassment. *Female genital mutilation* is the percentage of women who have undergone female genital mutilation.

The *Son Preference* subindex reflects mainly the economic valuation of women. Its only component is the variable *Missing women* that measures gender bias in mortality. Countries were coded by Stephan Klasen based on estimates of gender bias in mortality for a sample of countries (Klasen and Wink, 2003) and on sex ratios of young people and adults.

The *Ownership rights* subindex covers the access of women to several types of property. *Women's access to land* indicates whether women are allowed to and can de facto own land. *Women's access to bank loans* measures whether women are allowed to and can de facto access

³ The data cover more than 100 countries and are available at the web-pages <http://www.wikigender.org> and <http://www.oecd.org/dev/gender/gid>.

⁴ Acceptance of polygamy in the population might proxy actual practices more than the formal indicator legality of polygamy and, moreover, laws might be changed faster than practices. Therefore, the acceptance variable is the first choice for the subindex Family code. The reason for using legality when acceptance is missing is to increase the number of countries.

credits. *Women's access to property other than land* covers mainly access to real property such as houses, but also any other property.

In all cases, the variables are between 0 and 1. The value 0 means no or very low inequality and the value 1 indicates high inequality. Three of the variables (Early marriage, Female genital mutilation and Violence against women) are continuous. The other indicators are on an ordered categorical scale.

Construction of the SIGI and its Subindices

The Construction of the SIGI

The SIGI is an unweighted average of a non-linear function of the subindices Family code, Civil liberties, Physical integrity, Son preference and Ownership rights. Its values are between 0 and 1, with 0 meaning no inequality and 1 indicating complete inequality.

The non-linear function arises because it is assumed that inequality related to gender corresponds to deprivation experienced by the affected women, and that deprivation increases more than proportionally when inequality increases. Thus, high inequality is penalized in every dimension. Additionally, the non-linearity has the advantage that the SIGI allows only for partial compensation among its components. Partial compensation implies that high inequality in one dimension, i.e. subindex, can only be partially compensated with low inequality on another dimension.

The non-linearity in the index is achieved by squaring the distance of the respective subindex value from 0, the goal of no inequality.⁵ The sum of the resulting squared subindex values divided by the number of subindices then gives the value of the SIGI. This implies a choice of equal weights for the subindices because there is no obvious reason to value one of the measured dimensions more or less than the others.

The value of the SIGI for a given country is calculated as follows:

$$SIGI = \frac{1}{5} (SubindexFamilyCode)^2 + \frac{1}{5} (SubindexCivilLiberties)^2 + \frac{1}{5} (SubindexPhysicalIntegrity)^2 + \frac{1}{5} (SubindexSonPreference)^2 + \frac{1}{5} (SubindexOwnershipRights)^2$$

The Construction of the Subindices

The five subindices Family Code, Civil liberties, Son preference, Physical integrity and Ownership rights use the twelve variables as input that were mentioned in the previous section.

⁵ The distance to 0, the goal of no inequality to be reached in the case of social institutions related to gender, is analogous to the distance to the poverty line in the Foster-Greer-Thorbecke poverty measures (Foster, Greer, and Thorbecke, 1984). It is an intuitive way to think about gender inequality. It must be noted, however, that unlike it is the case when one is dealing with variables such as income, here a lower value of the subindex is preferred.

Each subindex combines variables that measure one dimension of social institutions related to gender inequality.⁶

In the case of Son preference, the subindex takes the value of the variable Missing women. In all other cases, the computation of the subindex values involves two steps. First, the method of polychoric principal component analysis is used to extract the common information of the variables that belong to a subindex in the form of the First Principal Component (FPC), which is a weighted sum of the standardized corresponding variables. The weights are shown in Table 1.⁷ Second, the subindex value is obtained rescaling the FPC so that it is between 0 and 1 to ease interpretation. A country with the best possible performance (no inequality) is assigned the value 0 and a country with the worst possible performance (highest inequality) the value 1. Hence, the subindex values of all countries are between 0 and 1.⁸

Results

In section ‘Country Rankings’ the results for the SIGI and its five subindices are presented. Among the 102 countries considered by the SIGI⁹ (Table 2) Paraguay, Croatia, Kazakhstan, Argentina and Costa Rica have the lowest levels of gender inequality related to social institutions. Sudan is the country that occupies the last position, followed by Afghanistan, Sierra Leone, Mali, and Yemen which means that gender inequality in social institutions is a major problem there.

Rankings according to the subindices are as follows. For Family code (Table 3) 112 countries can be ranked. Best performers are China, Jamaica, Croatia, Belarus and Kazakhstan. Worst performers are Mali, Chad, Afghanistan, Mozambique and Zambia. In the dimension Civil liberties (Table 4) 123 countries are ranked. Among them 83 share place 1 in the ranking. Sudan,

⁶ Kendall’s Tau b, which is a statistical measure of association (Agresti, 1984), and graphics based on Multiple Correspondence Analysis (Greenacre, 2007; Nenadić, 2007) confirmed that within each of the five dimensions all the variables seem to measure the same underlying concept.

⁷ Polychoric principal component analysis (PCA) is a method of dimensionality reduction for categorical variables (Kolenikov and Angeles, 2004, 2009). Principal components are weighted sums of the standardized variables. In the case of continuous variables, one subtracts the mean and then divides by the standard deviation. In the case of categorical variables, the standardization uses results of an ordered probit model. The weight each variable gets in these linear combinations is obtained by analyzing the correlation structure in the data. The first principal component explains the largest amount of variation in the data.

⁸ Given the score of the first principal component the subindex is calculated using the following transformation. Country X corresponds to a country of interest, Country Worst corresponds to a country with worst possible performance and Country Best is a country with best possible performance.

$$Subindex(CountryX) = \frac{FPC(CountryX)}{FPC(CountryWorst) - FPC(CountryBest)} - \frac{FPC(CountryBest)}{FPC(CountryWorst) - FPC(CountryBest)}$$

⁹ The subindices are computed for countries that have no missing values on the relevant input variables. In the case of the SIGI only countries that have values for every subindex are considered.

Saudi Arabia, Afghanistan, Yemen and Iran occupy the last five positions of high inequality. 114 countries can be compared with the subindex Physical Integrity (Table 5). Hong Kong, Bangladesh, Chinese Taipei, Ecuador, El Salvador, Paraguay and Philippines are at the top of the ranking while Mali, Somalia, Sudan, Egypt and Sierra Leone are at the bottom. In the dimension Son preference (Table 6) 88 out of 122 countries rank at the top as they do not have problems with missing women. The countries that rank worst are China, Afghanistan, Papua New Guinea, Pakistan, India and Bhutan. Finally, 122 countries are ranked with the subindex Ownership rights (Table 7). 42 countries share position 1 as they have no inequality in this dimension. On the other hand the four worst performing countries are Sudan, Sierra Leone, Chad and the Democratic Republic of Congo.

To find out whether apparent regional patterns in social institutions related to gender inequality are systematic, we divided the countries in quintiles following the scores of the SIGI and its subindices (Table 8). The first quintile includes countries with lowest inequality, and the fifth quintile countries with highest inequality.

For the SIGI, no country of Europe and Central Asia (ECA) or Latin America and the Caribbean (LAC) is found in the two quintiles reflecting social institutions related to high gender inequality. In contrast, countries in South Asia (SA), Sub-Saharan Africa (SSA), and Middle East and North Africa (MENA) rank in these two quintiles. East Asia and Pacific (EAP) has countries with very low as well as very high inequality. It is interesting to note that in the most problematic regions some countries rank in the first two quintiles. These are Mauritius (SSA) and Tunisia (MENA).

Going on with the subindices the pattern is similar to the one of the SIGI. As more information is available for the subindices, the number of countries covered by every subindex is different and higher than for the SIGI. In the following some interesting facts are highlighted, especially countries whose scores are different than the average in the region.

- *Family code:* No country in ECA, LAC or EAP shows high inequality. SA, MENA and SSA remain problematic with countries with social institutions related to high gender inequality. Exceptions are Bhutan in SA, Mauritius in SSA and Tunisia and Israel in MENA.
- *Civil liberties:* Only three groups of countries using the quintile analysis can be generated with the first group including the first three quintiles. In SSA over one-half of the countries are now in the first group. Also in MENA there are some countries with good scores (Israel, Morocco and Tunisia). No country in SA is found in the first three quintiles of low and moderate inequality.
- *Physical integrity:* Best cases in the most problematic regions are Botswana, Mauritius, South Africa and Tanzania (SSA), and Morocco and Tunisia (MENA).
- *Son Preference:* Again only three groups of countries can be built by quintile analysis, with the first group including the first three quintiles. As in the case of Civil liberties most of the countries in SSA do not show problems. Missing women is mainly an issue in SA and

MENA. But in both regions there are countries that rank in the first group. These are Sri Lanka in SA, and Israel, Lebanon and Occupied Palestinian Territory in MENA.

- *Ownership rights*: Best cases in MENA are Egypt, Israel, Kuwait and Tunisia as they rank in the first quintile. This is also valid for Bhutan in SA, and Eritrea and Mauritius in SSA.

Discussion

Based on variables of the OECD Gender, Institutions and Development Database, the Social Institutions and Gender Index (SIGI) offers a new way to approach gender inequalities and to compare 102 non-OECD countries that has been neglected in the literature and by other gender measures.¹⁰ Together with the five subindices Family code, Civil liberties, Physical integrity, Son preference and Ownership rights it helps policy-makers to detect in what countries and in which dimensions of social institutions related to gender inequality problems need to be tackled. Moreover, the indices are valuable instruments to generate public discussion.

Any composite index is confronted with possible critiques of decisions and trade-offs regarding, e.g. the choice and treatment of the variables included, the weighting scheme, the aggregation method.¹¹ In the case of the SIGI such criticisable decisions have also been necessary. But these choices are transparent and clear. Moreover, the formula to compute the SIGI is easy to understand.

However, three caveats must be noted. First, the figures produced do not substitute a careful investigation of all the components of the SIGI and additional qualitative information that helps understanding the situation in each country. Second, as any composite index cannot be better than its components, it is worth investing in the measurement of social institutions related to gender inequality. For example, it would be interesting to exploit data available from the Demographic and Health Surveys (DHS) that specifically address the perception that women have of violence against women, and to finance further surveys in countries where data is not available yet. Third, the fact that OECD countries are not included in the SIGI sample does not mean that there are no social institutions related to gender inequalities in these countries, but they are not well captured by the variables used for the SIGI.

The SIGI and its subindices could influence current development thinking as they highlight social institutions that affect overall development. Preliminary results show that the SIGI and its

¹⁰ This is not only true from a theoretical perspective. An empirical analysis of the statistical association between the SIGI and other gender-related indices like the Gender-related Development Index, the Gender Empowerment Measure, the Global Gender Gap Index from 2007 and the Women's Social Rights Index indicates that the SIGI is correlated with these measures, but the correlation coefficients remain below a threshold that indicates redundancy. These results suggest that the SIGI provides additional information. Results as well as the country rankings of the SIGI and other measures can be found in Branisa et al. (2009).

¹¹ For a general discussion of the construction of composite indices, see Nardo, Saisana, Saltelli, Tarantola, Hoffman, and Giovannini (2005).

subindices are related to health and education of women even after controlling for the usual suspects region, religion and the level of economic development.¹²

¹² Results are available upon request.
