Total health spending accounted for 5.6% of GDP in Korea in 2004. Health spending as a share of GDP in Korea is the lowest among OECD countries, more than three percentage points lower than the OECD average of 8.9%. The United States (which spent 15.3% of its GDP on health in 2004) is, by far, the country that spends the most on health as a share of its economy.

Health spending tends to rise with income. In general, OECD countries with higher GDP per capita tend to spend more on health. It is not surprising therefore that Korea also ranks below the OECD average in terms of health spending per capita, with spending of 1150 USD (calculated based on purchasing power parity), compared with an OECD average of 2550 USD in 2004.
Real health expenditure per capita has nonetheless increased rapidly in Korea since the second half of the 1980s when national health insurance was established. During the 1990s, the rate of growth in health spending has been two-times greater than the average across OECD countries. This trend continued between 1999-2004, when Korea experienced an average real growth of health spending of 8.9% per year, exceeding the OECD average of 5.2%. The increase in total health spending in Korea has been driven mainly by a rapid rise in public spending on health.

The rise in pharmaceutical spending has been one of the factors behind the rise in total health spending in many OECD countries in recent years. In 2004, spending on pharmaceuticals accounted for 27.4% of total health spending in Korea, one of the highest shares in the OECD area and well above the OECD average of 17.7%. In per capita terms, however, pharmaceuticals spending (adjusted by purchasing power parity) in Korea remains much lower than the OECD average and less than half the spending in the United States.

Although the share of public spending on health in Korea steadily increased during the past decade, rising from 38% of total health spending in 1990 to 51% in 2004, it remains well below the OECD average of 73%. Among OECD countries, the share of government spending on health is the lowest in the United States (45%), followed by Mexico (46%) and Korea. It was relatively high (over 80%) in several Nordic countries (Denmark, Norway and Sweden), the United Kingdom and Japan.

The relatively high private share of health funding in Korea is linked to substantial out-of-pocket payments, which account for 37% of total health spending. This is in sharp contrast with the situation in the United States, where the bulk of private spending is paid by private health insurance arrangements, leaving only 13% of total health spending paid directly by consumers.

**Resources in the health sector (human, physical, technological)**

The number of doctors per 1 000 population in Korea was 1.6 in 2004, the second lowest among OECD countries after Turkey and well below the OECD average of 3.0. However, the number of doctors has increased rapidly over the past two decades. Korea registered in fact the highest growth rate in the number of doctors among all OECD countries, with the number of doctors per capita doubling between 1990 and 2004. This rise is expected to continue in the years ahead as a result of newly established medical schools and higher number of medical students.

As for doctors, the number of nurses per capita in Korea remains much lower than in most other OECD countries (1.8 in 2004, compared to an OECD average of 8.3). But the number of nurses per capita increased significantly in Korea in the past decade, up from 1.1 in 1994.

The number of acute care beds in hospitals in Korea was 5.9 per 1 000 population in 2003 (latest year available), higher than the OECD average of 4.1. While the number of acute care hospital beds is being reduced in most other developed countries, they have been growing rapidly during the past decade in Korea. This fast growth can be linked in part with the lack of capacity planning for hospital beds in a private, for-profit dominated health delivery system, and in part with the non-differentiation between chronic and acute care beds.

The average length of stays for acute care in hospitals in Korea is the second highest among OECD countries, after Japan. It was 10.6 days in 2003, well above the OECD average. This relatively high average length of stays in hospitals can be explained in part by the lack of beds for long-term care; hence acute care beds may also be used for chronically ill patients. The growing number of hospital beds might also have given Korean hospitals incentives to keep patients longer.
During the past decade, there has been a rapid growth in the availability of diagnostic technologies such as computed tomography (CT) scanners and magnetic resonance imaging (MRI) in most OECD countries. Korea was no exception. The number of CT scanners per million population increased rapidly in Korea, from 12.2 in 1990 to 31.5 in 2004. Similarly, the number of MRIs per million population also increased at a fast pace, from 1.4 in 1990 to 11.0 in 2004. Japan is, by far, the country which reports the highest number of CT and MRI scanners per capita, with 93 CT scanners and 35 MRI per million population.

**Health status and risk factors**

Most OECD countries have enjoyed large gains in life expectancy over the past forty years, thanks to improvements in living conditions, public health interventions and progress in medical care. Among OECD countries, Korea registered the greatest gains in life expectancy between 1960 and 2003, with an overall increase in longevity of 25 years, rapidly narrowing the gap with the average across OECD countries. In 1960, life expectancy in Korea was 16 years below the OECD average. By 2003, it stood at 77.4 years, less than one year below the OECD average.

The proportion of daily smokers among adults has shown a marked decline over recent decades across most OECD countries. In Korea, there remains however a huge gender gap in smoking rates between men and women: 61.8% of men reported to smoke every day in 2001, the highest rate across all OECD countries, compared with only 5.4% in 2001 of women, which is the lowest rate.

Obesity rates have increased in recent decades in all OECD countries, although there remain notable differences across countries. The obesity rate in Korea and Japan remains the lowest among OECD countries, with 3.2% only of the adult population defined as obese in 2001. The countries with the highest adult obesity rates include the United States (30.6% in 2002) and the United Kingdom (23% en 2003).1

---

1 It should be noted however that the data for the United States and the United Kingdom (as well as for Australia, New Zealand, and Canada for the year 2004) are more accurate than those from other countries since they are based on actual measures of people’s height and weight, while estimates for other countries are based on self-reported data, which generally under-estimate the real prevalence of obesity.
