ABOUT THE OECD

The Organisation for Economic Co-operation and Development (OECD) is an intergovernmental organisation in which representatives of 30 industrialised countries in North America, Europe and the Pacific, as well as the European Commission, meet to co-ordinate and harmonize policies, discuss issues of mutual concern, and work together to respond to international problems. Most of the OECD's work is carried out by more than 200 specialised Committees and subsidiary groups composed of Member country delegates. Observers from several countries with special status at the OECD, and from interested international organisations, attend many of the OECD's Workshops and other meetings. Committees and subsidiary groups are served by the OECD Secretariat, located in Paris, France, which is organised into Directorates and Divisions.

The Environmental Health and Safety (EHS) Division publishes documents in eight different series: **Testing and Assessment; Good Laboratory Practice and Compliance Monitoring; Pesticides; Risk Management; Harmonization of Regulatory Oversight in Biotechnology; Chemical Accidents; Pollutant Release and Transfer Registers; and Emission Scenario Documents.**

The Environmental Health and Safety Programme co-operates closely with other international organisations. This document was produced within the framework of the Inter-Organization Programme for the Sound Management of Chemicals (IOMC).

The Inter-Organization Programme for the Sound Management of Chemicals (IOMC) was established in 1995 by UNEP, ILO, FAO, WHO, UNIDO and the OECD (the Participating Organizations), following recommendations made by the 1992 UN Conference on Environment and Development to strengthen co-operation and increase international co-ordination in the field of chemical safety. UNITAR joined the IOMC in 1997 to become the seventh Participating Organization. The purpose of the IOMC is to promote co-ordination of the policies and activities pursued by the Participating Organizations, jointly or separately, to achieve the sound management of chemicals in relation to human health and the environment.

This publication is available electronically, at no charge.

Explanatory notes

Purpose and background

This OECD Emission Scenario Document (ESD) is intended to provide information on the sources, use patterns and release pathways of chemicals used as additives in rubber industry to assist in the estimation of releases of chemicals to the environment.

This ESD should be seen as a ‘living’ document, which provides the most updated information available. As such, an ESD can be updated to take account of changes and new information, and extended to cover the industry area in countries other than the lead (Germany). Users of the document are encouraged to submit comments, corrections, updates and new information to the OECD Environment, Health and Safety Division (env.riskassessment@oecd.org). The comments received will be forwarded to the OECD Task Force on Environmental Exposure Assessment, which will review the comments every two years so that the lead country can update the document. The submitted information will also be made available to users within the OECD web-site (www.oecd.org/env/riskassessment).

How to use this document

The user of this ESD needs to consider how the information contained in the document covers the situation for which they wish to estimate releases of chemicals. The document could be used as a framework to identify the information needed, or the approaches in the document could be used together with the suggested default values to provide estimates. Where specific information is available it should be used in preference to the defaults. At all times, the values inputted and the results should be critically reviewed to assure their validity and appropriateness.

For the estimation of the emissions of chemicals used as additives in the rubber industry the following data and information should be available:

- function of the additive
- type of rubber product
- amount of rubber product produced per day (default)
- percentage of additive introduced into the rubber product
- fraction of additive remaining in the rubber product (default).

Coverage

This ESD describes the life cycle stages of rubber additives in formulation, use, and service life (tyre abrasion), and provides emission estimations to local surface waters, air and soil. The industry categories, use categories and biocidal product types relevant to this document are as follows.

Industry category	Use Category	Biocidal product type
11 – polymer industry	20 – fillers 22 – flame retardants and fire preventing agents 49 – stabilisers 53 – vulcanising agents	

How this document was developed

In the year 1999, Umweltbundesamt (UBA Germany) commissioned the Institute for Environmental Research, University of Dortmund (INFU) (contract no 360 01 27/3; <http://www.oekopro.de>) to develop this ESD. In 2001, Umweltbundesamt integrated comments received from RIVM (The Netherlands) and adjusted the nomenclature to the agreed EU nomenclature (<http://ecb.jrc.it> - biocides). This ESD was published in the European Union Technical Guidance Document on Risk Assessment [EU 2003, Part IV].

Germany (Umweltbundesamt) as the lead country submitted this draft to OECD, and the draft was circulated to the member countries in February 2002. Comments were received from the following organizations and institutions: UK (Environment Agency and Health and Safety Executive), US EPA and US industries, Canada [OECD, 2002]. Umweltbundesamt incorporated these comments in consultation with the Institute for Environmental Research, University of Dortmund (INFU) and the Association of the German Rubber Industry and amended the document with two new sections:

- Emission scenario for formulation and processing to air and soil
- Emission scenario for use of rubber products by tyre abrasion (service life).

Releases from leachates in landfill and to sea or fresh water are not covered yet and need to be considered in the next version.

The OECD Task Force for Environmental Exposure Assessment concluded at its 10th session (8 April 2003) that this ESD is to be subsumed under the Industry Category 11 “Polymer Industry” new subsection “rubber additives”.

1. INTRODUCTION

1. This document provides guidance for estimation of emissions from chemicals used as additives in the rubber industry (IC-11 Polymer industry), including additives like vulcanising agents (UC-53), anti ageing agents, fillers (UC-20), pigments, stabilizer (UC-49), plasticisers, processing aids, flame retardants (UC-22).

2. The emissions during “industrial use” depend on the type and formulation of the additive and the processes. The two life-cycle phases “formulation” and “industrial use” can often not be separated and are therefore combined for this emission estimation. The processing steps taken into account are:

- the creation of the rubber mixture
- the mastication
- the shaping
- the vulcanisation
- the finishing

3. Additives may enter the environmental compartments water, air, and soil. The major pathway is the entry into water. This occurs in those processes, where water is used as cooling or heating medium, in vulcanisation, where water has direct contact with the rubber mixture. Releases to water can also occur in cleaning steps throughout these processes. The water pathway is the predominant one and is described in this document by a generic point source. For most additives, the air pathway is of minor importance.

4. A regional scenario of tyre abrasion describes the phase „service life“ with subsequent leaching into surface water and soil. The phase “waste disposal” means the leaching potential by rainwater to the soil and water compartment or when used tyres are in contact with fresh or marine water. Mainly volatile monomers and plasticisers escape to the air compartment. A waste disposal scenario is not covered in this document.

2. INDUSTRY SUMMARY AND BACKGROUND

5. The EU produces only synthetic rubber. The total production of synthetic rubber amounted to 2.51 million tonnes in the year 2001 (International Rubber Study Group 2003). This is about 25% of the world production. Unlike natural rubber, synthetic rubber is subject to strong fluctuations in the amount used and produced. This raw material was used to produce about one million tonnes of tyres and about 530.000 tonnes of rubber products (“technical and other elastomer products”) in 1995. Table 1 shows the production of different EU countries, and Table 2 provides the market share of different synthetic rubber types characterised by the monomers used in the production. The world production of natural rubber grew from 3 million tonnes (1980) to 7.13 million tonnes in 2001 (International Rubber Study Group 2003).

Table 1 Production and Consumption of Rubber (1996)

Country	synthetic rubber production [1000 tonnes]	synthetic rubber consumption [1000 tonnes]	natural rubber consumption [1000 tonnes]
Spain	83.7	0	124.9
Italy	317.2	349	119.4
Turkey	40.1	0	0
France	565.8	403.6	209.7
Belgium	139.6	0	51.9
Germany	573.4	611.3	211.8
Netherlands	215.7	0	66.6
United Kingdom	306	268.9	140.4

3. MAIN PROCESSES

7. It is helpful to define three terms that are used in the rubber industry [Ullmann 1993]:

- **Rubber** (raw rubber) is a non-cross-linked, but cross-linkable (curable, vulcanisable) polymer with rubber-elastic properties at room temperature. At higher temperatures and/or, if exposed to deforming forces, rubber demonstrates an increasing tendency for viscous flow. Therefore, it can be formed under appropriate conditions.
- **Elastomers** are polymeric material that is cross-linked (vulcanised). They are hard and glassy at low temperature and do not exhibit viscous flow even at high temperature. Rubber elastic behaviour is characterised by a relatively low shear modulus with comparably low temperature dependency.
- **Vulcanisation** is a process in which rubber, through a change in its chemical structure (for example, cross-linking) is converted to a condition, in which the elastic properties are conferred or re-established or improved or extended over a greater range of temperature.

8. Natural rubber differs from synthetic rubber. Natural rubber is made from the milk of the rubber tree. This rubber milk is also called latex and is a colloidal dispersion in an aqueous medium. The latex concentration after tapping is about 30%. Only a small percentage is used directly; the greatest part is processed into harder rubber. This is done through evaporation, hydro extracting, creaming and electro decanting. Thailand is the most important producer of natural rubber. The raw rubber material is exported into the processing countries in the solid form.

9. Natural rubber demonstrates a balanced combination of physical attributes resulting in a broad range of possible uses [Ullmann 1993]. A certain synthetic rubber surpasses every single attribute of a natural rubber. If these attributes are specifically required, the appropriate synthetic rubber will be used instead of the natural rubber.

10. The most important types of synthetic rubber are shown in Table 2 in relation to their market shares. Almost two thirds of the total rubbers currently used in industry are synthetic. These rubbers are made from monomers like butadiene, styrene, acrylonitrile and isobutene. Table 4 characterises the attributes of these rubbers. There are many more synthetic rubbers than shown in the Table [Baumann and Ismeier 1998; Ullmann 1993].

11. Depending on the production procedure, one differentiates between polymerisates, polycondensates and polyaddition products. According to DIN ISO 1629 rubbers in the form of hard rubbers and latex are divided into groups depending on the chemical structure of the polymer chains. The rubber types are divided by their attributes [Lüpfert 1990] and their functions [Rentel et al. 1991]. A rubber is made mainly of [Lüpfert 1991]

- polymers (elastomers)
- fillers
- plasticisers

- anti ageing agents
- linking systems.

12. Additives are added before and during processing. After the initial composition the mixture is created with an internal mixer, a rolling mill, a batch-off-facility and an extruder. The shaping of the semi-finished product is made with an extruder, a plunger type injection moulder, through calendaring, the spreading machine and assembly.

13. The compression process, the transfer moulding, and injection moulding are used for vulcanisation (curing) in presses. A continuous vulcanisation is made with the rotational vulcanisation, the steam pipe vulcanisation, the hot-air vulcanisation with microwave preheating, the boiling bed vulcanisation and the salt-bath vulcanisation. In addition to these, vulcanisation can also be accomplished in an autoclave.

Table 4 Rubber Type and Additives

3.1 Natural- and synthetic Rubber

3.1.1 Mastication and Creation of Mixtures

14. The mastication is a process, in which the length of the polymer chains is decreased to lower the viscosity. This is necessary to get a better workability of the rubber (extrusion, calender and others) and to spread the rubber chemicals throughout the matrix. Rubber additives like anti ageing agents, fillers, plasticisers are discussed in Subsection 3.4. Their functions are shown in Table 5.

15. An optimised viscosity is especially important for the production of rubber blends, since a homogenous distribution of the constituents is only possible within an equal viscosity. Unlike synthetic rubber, which can often be processed without a previous mastication, natural rubber is usually offered as a relatively hard product with little plasticity, making mastication a requirement.

16. The mastication can be achieved in a purely mechanical process, in a mechanic-thermal process, physically by adding plasticisers and/or processing agents as well as chemically.

17. Machines like rolling mills, the internal mixer or the gordon-plasticator masticate the rubber substance but also serve as mixers, for cooling, to finish the mixing of half ready rubber mixtures and to preheat finished rubber mixtures. A possible contamination of the water compartment during the mixing process can happen through the cooling process, if water is used as a direct cooling agent. Finally sulfur is added to the mixture. The finished mixture is taken off as a rough sheet. This rough sheet is cooled by immersion in water to which an anti tack-agent has been added (rolling mill). Especially in larger companies, the internal mixer replaced the rolling mill. An internal mixer can hold 15 to 650 litres. For the homogenisation, cooling and working into sheets rolling mills are still used. In modern installations, a batch off machine is responsible for taking off the sheets and immersing them in a bath of water or a bath with an anti tack-agent.

3.1.2 Shaping

18. Rubber mixtures are usually not immediately reprocessed after the mixture was created, but are stored in a cool and dry environment. For the shaping, processes like extrusion, calendaring, form moulding and transfer moulding are used.

19. Injection machines (extrusion plants) form rubber mixtures into bars, tubes, profiles, treads of tyres or sheets or encase cables and wires. In a continuous process, the rubber mixture is cured immediately after extrusion. If reprocessing as a semi-finished product is planned, the mixture is dusted and drawn through an adherent bath. Calendaring is used to create sheets for the rubberisation of technical weaves (fractioning) and to coat weaves with a thin rubber sheet (skimming).

20. Formed articles are mass articles like stoppers, bottle caps, soles, packing rings, collars, membranes, valve balls, buffers and tyres. Processes like pressing, transfer moulding, flashless-processes and the injection-moulding process are characterised by shaping and vulcanisation in one step. An assembly line takes an important role in this context.

21. After the forms were used in a transfer moulding process over time, organic residues from the rubber mixture or from the anti tack-agents deposit as incrustation or carbonisation. A chrome sulfur bath (60°C) is used to clean the forms. The actual cleaning takes place in a lapping machine with a suspension of quartz flour. Water is used for rinsing the cleaned forms.

3.1.3 Vulcanisation / Curing

22. Vulcanisation is a chemical process to link the polymer structure. The term vulcanisation is used for a linking procedure, during which the macromolecules of the rubber are linked to each other over linking bridges. The linking is achieved with vulcanisation agents, usually sulfur, sulfur producers or peroxides as well as energy rich radiation.

23. If uncured, rubber is thermoplastic. The molecules are not connected to each other. During vulcanisation the rubber changes from the thermoplastic to the elastic condition. The number of links depends on the amount of linking substances, their activity and reaction time. The following procedures are used for vulcanisation:

- liquid curing method (LCM-Vulcanisation)
- boiling bed vulcanisation
- hot air vulcanisation after UHF-preheating
- vulcanisation in hot steam under high voltage (under lead).

24. The LCM-vulcanisation is commonly used for extruded profiles, tubes and similar processes. It is continuous and takes place in a liquid bath. The duration of the bath depends on the vulcanisation speed, the injection performance of the extrusion plant, the temperature of the heating bath and other factors. Eutectic salt mixtures (as well as glycerin, silicon oils, polyalkyleneglycole, metal mixtures) are used as a heating medium. For the boiling bed vulcanisation, small glass beads are used through which gas flows to lift them.

25. The HF vulcanisation uses a pressure-free continuous process. The vulcanisation in steam pipes is used almost exclusively in the cable industry. Immediately after coating, the cable is guided into a pipe,

in which the steam pressure is usually between 0,5 and 1,2 MPa (max. 2 MPa). To reduce deformations, the vulcanisation is sometimes performed under a lead coating, this coating protects from the hydrolytical effect of the steam. After cooling with water, the lead coat is removed.

26. The vulcanisation of calendared products can be achieved with rotational vulcanisation or in vulcanisation presses. A high frequency preheating is possible. Assembled rubber products are vulcanised free (not in a mould) in an open heater (hot air vulcanisation).

27. To decrease the vulcanisation time, a steam heater is used. When using saturated vapour, in which water and steam are in balance, the temperature transference is more even. To avoid condensation spots, spreading agents are used. When vulcanising in water, the temperature transfer is extremely good compared to a medium of air or steam. This process will be used for big parts. It is used rarely for example for the vulcanisation of large rolls due to the complexity of the process. Vulcanisation can also be achieved through cold vulcanisation or energy rich radiation.

3.2 Latex

28. Natural latexes and synthetic latexes (as are created during the emulsion polymerisation) are processed, among other things into thin-walled products. The mixture is prepared by kneading the required chemicals into the latex solution. The coagulation process is used to create thick-walled products. The form is submerged in an alcoholic solution of a coagulation substance. This results in a thicker coagulum on the form as in other submerging processes. The vulcanised products must then be thoroughly rinsed with water to remove the coagulation substance.

29. For foam rubber, steam or hot water is used as a medium for the vulcanisation. The spinning process for the creation of latex strings also requires water to rinse out the coagulator.

30. Products made from unwoven textiles are made from bonded fabrics impregnated with a latex mixture. The unused adhesive is pressed out and the damp fabric dried and vulcanised. Leftover chemicals (emulsifying agents, stabilisers) are removed by washing.

3.3 Rubber-Metal

31. Metal working takes place in the rubber industry wherever composite parts made of rubber and metal are needed. One example is the tyre, which, in addition to a multitude of rubber mixtures, includes stabilising material like steel, textiles or plastic. Other rubber-metal parts for the automobile industry are shock absorbers, elastomere springs, coupling parts, hangers and others. Rubberised parts, like rolls are used in other areas. For the preparation of composite parts, spray- and degreasing plants are used.

3.4 Chemicals and Additives

32. The rubber industry uses hundreds of different substances. The finished product gains the required attributes only by adding fillers, plasticisers, vulcanisation chemicals, anti ageing agents and adhesives. Table 5 lists the most important process steps for the production of rubber and the most important substance classes used in each step.

33. The rubber industry uses a special unit for expressing the components of a rubber mixture. They are presented in relation to 100 mass parts total rubber (parts per hundred rubber [phr]) or in wt-% (cf. Table 9)

Table 5 Functions of Additives in Rubber Processing Steps

Process Step / Additive	Description	Function of the Chemicals used
Mastication	plastification of the rubber before working the molecular chain splitting through oxidative breakdown (usually aromatic or heterocyclic mercaptan). By using activators, the mastication can be shifted to a lower temperature spectrum (inner complex salts).	1. mastication agents 2. activators (Boosters)
Vulcanisation	For linking the rubber molecules And creating linking bridges (usually sulfur,	Vulcanisation agents Vulcanisation accelerators Vulcanisation activators
Vulcanisation	Sulfur producers, peroxides)	Vulcanisation retarders
Anti-ageing agents	finished product with protection against damaging influences.	1. antioxidants
		2. anti fatigue agents 3. anti ozonants 4. light protection agents 5. anti hydrolysis agents 6. agents against metal poisoning 7. desactivators 8. reversion protection agents 9. anti cyclisation agents
Fillers	substances which are insoluble towards the rubber matrix, non-volatile and inert towards the polymer. The fillers define the attribute of the vulcanisate. They extend and strengthen the vulcanisate.	inorganic fillers organic fillers
Plasticisers	plasticisers serve as extensions, they improve the fluidity, they distribute the fillers, improve the workability and the adhesiveness. They influence the physical attributes of the rubber like expansion and elasticity. Primary plasticisers have a loosening effect and lower the viscosity of non-vulcanisated rubber mixtures. Secondary plasticisers serve as lubricants and improve the shapeability.	Plasticisers (categories: mineral oils, natural substances, synthetic plasticisers)
Pigments/ Colourants	pigments are in rubber de facto insoluble, organic or inorganic, coloured or white substances.	1. inorganic pigments: a) white pigments b) coloured pigments □ organic pigments
Processing aids	processing aids ease the working of the material: 1. lubricants are used mainly in the extrusion and the injection moulding processes	1. lubricants Metal soaps (like zinc-, calcium-soaps) Aliphatic acids, Aliphatic acid ester

Process Step / Additive	Description	Function of the Chemicals used
	2. tackifiers serve to increase the assembly adhesion	2. tackifier
Processing aids	3. among others to improve the stability, the injectability and calendrability	3. factice
Processing aids	4. by using fillers activators, the activity of the fillers can be improved	4. fillers activators, adhesion agents
	5. blowing agents are used to produce porous rubber articles (decompose under gas splitting) 6. bonding agents increase the adhesion of rubber on strengthening material (weaves, metal)	5. blowing agents □ inorganic □ organic 6. bonding agents
other agents	1. anticyclisation agents serve to prevent unwanted cyclisation during mastication 2. with the aid of replastication agents slightly vulcanized mixtures can be returned to a workable condition (desulfuring of the rubber mixture) 3. emulsifier disperse systems 4. flame retardant lower the flammability of the rubber 5. in solvent adhesives, in solvent dipping processes, for cleaning 6. for refining the surface 7. to increase the hardness of the vulcanisate 8. to nuance, neutralize and cover the rubber smell 9. to increase the electronic conductivity 10. to kill microorganisms 11. to prevent the spreading of germs	1. anti cyclisation agents 2. replastication agents 3. emulsifier 4. flame retardant 5. solvents 6. surface treatment agents 7. hardeners 8. odorants 9. antistatic agents 10. microbiocides 11. anti termite agents
Latex-chemicals	to add pulverised additives into the aqueous colloidal latex Solution	1. dispersion agents 2. emulsifier 3. stabiliser 4. wetting and foaming agents 5. foam stabilisers 6. thickeners 7. coagulating agents 8. preservatives 9. vulcanisation chemicals
Latex-chemicals		10. anti ageing agents 11. fillers 12. plasticisers

Process Step / Additive	Description	Function of the Chemicals used
Release agents	<ol style="list-style-type: none"> 1. prevent non-vulcanised rubber mixtures from adhering during storage 2. prevent rubber from sticking to the forming tools 3. release agents are added to the rubber mixture, migrate to the surface and improve the removability of the vulcanisate from the form 	<ol style="list-style-type: none"> 1. release agents for non-vulcanised rubber mixtures (anti tack agents) 2. mould release agents 3. mandrel release agents

4. EMISSION SCENARIOS

34. This document describes three generic emission scenarios:

- formulation and processing: emissions to wastewater
- formulation and processing: emissions to air and soil
- private use of rubber products by tyre abrasion: emissions to surface water and soil.

35. The contamination of water in the rubber industry takes place in several phases of the rubber production, whenever water comes into direct contact with the rubber product. This happens during cooling-, heating-, vulcanisation- and cleaning operations. Examples are direct cooling during the extrusion or direct contact of the material vulcanised with the steam in the vulcanisation processes.

36. The sources and possible contaminations of wastewater are presented in Table 6. The water can contain zinc (zinc compounds are often used in anti tack agents), cadmium, copper and lead from vulcanisation. Storing, weighing, mixing are other possible sources of exposure.

37. By using wastewater free procedures (indirect cooling, circulation systems, dry cleaning) releases to water can be avoided. A cascading arrangement of the rinsing baths and an optimised water flow can also decrease the volume of wastewater. The remaining wastewater is treated, if the pollutant concentration makes it necessary. Degreasing is accomplished with chlorinated hydrocarbons and complex builders like EDTA. The reduction or prevention of hazardous substances from the cleaning operations can be accomplished by degreasing on an aqueous basis.

Table 6 Water Contamination of different Sources in the Rubber Industry [in mg.L⁻¹] (Association of the German Rubber Industry 1999) ¹

4.1 Definition of the generic Point Source

38. The generic point source for the rubber industry derived in this sub-chapter is related to the German situation. However, it is believed that the size of a typical manufacturer in the EU Member states is comparable, because of the general structure of the rubber industry. This generic point source is the reasonable worst case used in the environmental exposure assessment. Similar considerations can be followed in deriving the generic point source in non-EU Member states of the OECD.

39. The emissions of the generic point source are derived from a survey of the wastewater discharges in the rubber industry. This total wastewater stream can be divided into the following component waste streams: sanitary, rainwater, metalworking, rubber working and others. The total quantities discharged each day are shown in Figure 1. The Association of the German Rubber Industry (1999) provided these discharge volumes and the following assumptions.

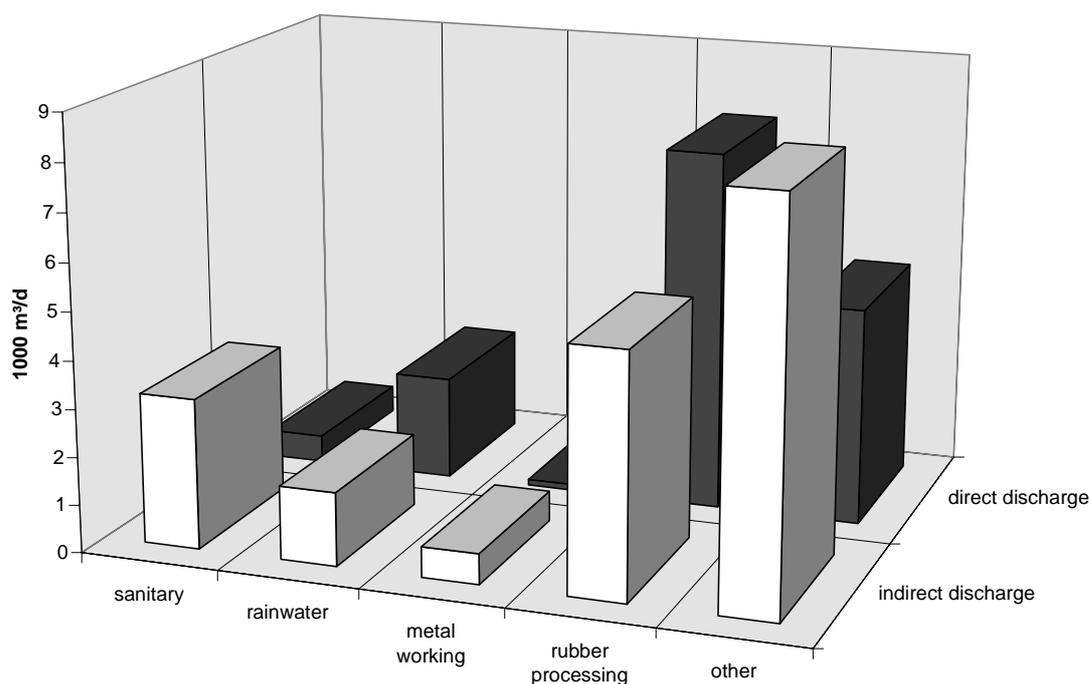

Figure 1 Volume of Component Wastewater Streams of direct and indirect Discharge for Members of the Association of the German Rubber Industry (1999)

40. The Association of the German Rubber Industry (1999) recorded these wastewater data for 18 direct dischargers (facility owned sewage treatment plant) and 70 indirect dischargers (via the municipal sewage treatment plant), 88 companies in total. It should be noted, that three companies discharged 75% of the total volume directly, and one indirect discharger made up for 30% of the corresponding discharge. This wastewater volume covers not only the rubber processing, but also the sanitary, metalworking and other areas. It is assumed that 37 % of the wastewater is attributed to rubber processing. Table 7 lists the statistical wastewater data for determining the generic point source.

Table 7 Statistical Data for determining the generic Point Source

Quantity of Wastewater (1)	Flow rate [$\text{m}^3 \cdot \text{d}^{-1}$]
Q_{wwat} (arithmetic average)	184
Q_{wwat} (minimum)	10
Q_{wwat} (maximum)	1154
Q_{wwat} (90-percentile)	438

(1) Sample size of 84 companies

41. Direct and indirect discharges were combined. The EU standard sewage treatment plant with a flow rate of $2000 \text{ m}^3 \cdot \text{d}^{-1}$ was used to eliminate from this sample those companies with a higher flow rate. 84 companies were below this threshold and discharged in total about $15000 \text{ m}^3 \cdot \text{d}^{-1}$. Four very large companies that were above this threshold and discharged in total also about $15000 \text{ m}^3 \cdot \text{d}^{-1}$. These four companies were eliminated in the evaluation of the 90 percentile. The 90 percentile value is $438 \text{ m}^3 \cdot \text{d}^{-1}$.

42. It was further assumed that about 3 m^3 water are needed to produce one tonne of rubber goods. This water consumption accounts only for the rubber production.

43. With the assumption that the water consumption of the rubber production is 37% of the value for the 90-percentile of the wastewater volume, a daily generic production (Q_{prod}) of about 55 tonnes per day is derived as the reasonable worst-case generic point source:

$$Q_{\text{prod}} (\text{generic point source}) [\text{t} \cdot \text{d}^{-1}] = Q_{\text{wwat}} (90 \text{ percentile}) [\text{m}^3 \cdot \text{d}^{-1}] * 0.37 / 3 [\text{m}^3 \cdot \text{t}^{-1}]$$

$$Q_{\text{prod}} (\text{generic point source}) [\text{t} \cdot \text{d}^{-1}] = 438 \text{ m}^3 \cdot \text{d}^{-1} * 0.37 / 3 \text{ m}^3 \cdot \text{t}^{-1} = 55 \text{ t} \cdot \text{d}^{-1}$$

44. A further assumption is that the production ratio for tyres: rubber products is 60 : 40. This assumption is presented in Table 8. The quantities compiled in this table are also used in example calculations (Section 5).

Table 8 Product Type and Amount produced at the generic Point Source

Product type	Amount Q_{prod} [kg.d⁻¹]
Tyres	33000
tyres total	26400
car tyres	11600
Truck tyres	14800
re-treading	6600
rubber products	22000
technical tubes, profiles	5320
form products, rubber-metal compounds	5190
glues, mixtures, repair materials	2840
foam-, micro cellular- and cellular rubber products	2110
conveyor belts, flat- and vee belts	1940
sole material	550
sheet material, punching products	460
other technical products	1150
other rubber products	2440
Sum	55000

4.2 Emission Rate Estimation

45. The emission scenarios are presented in the following way.

Input

[Variable/parameter (unit)] [Symbol] [Unit] [Origin: A/D/O/P]

These parameters are input to the scenario. The A, D, O, or P classification of a parameter indicates the status:

- A Parameter must be present in the input data set for the calculation to be executed. The applicant delivers it. Normally, there is no default value.
- D Parameter is a standard default value.
- O Parameter is the output from a calculation.
- P Parameter is chosen from a “pick-list” of values.

Output

[Symbol] Description

4.3 Emission Scenario for Formulation and Processing to Wastewater

46. The following information is needed for the emission calculation of the releases to wastewater:

- function of the additive (Table 9)
- product type and amount produced per day [kg/d]. The default values for tyres and different rubber products and their sub-divisions are presented in Table 8.
- additive introduced. This figure is either given in weight percent [wt-%] or in parts per hundred rubber [phr]. The latter figure is a special term used in the rubber industry (cf. Table 10). This figure can either be delivered by the applicant (A) or can be taken as default (D) from Table 9.
- fraction of additive remaining in the rubber product. This figure can either be provided by the applicant or be taken as default from Table 9.

47. The emission rate [kg/d] into wastewater is calculated from equation (1) as shown:

$$E_{local\ water} = Q_{prod} \cdot \frac{Q_{additive}}{100 \cdot F_{recipe}} \cdot (1 - F_{remaining}) \quad (1)$$

Parameter:

Explanation	Symbol	Value	Unit	Origin	Remarks
Input					
Amount of the product type produced per day	Q_{prod}		[kg.d ⁻¹]	P	see Table 8. If no detailed information is available the default of 55000 kg.d ⁻¹ is used from applicant or Table 9
Parts of additive introduced	$Q_{additive}$		[wt-%] or [phr]	A/P	
Recipe factor	F_{recipe}	2 resp. 1		A	2, when content is given in phr 1, when content is given in wt-% (see Table 10)
Fraction of additive remaining in the rubber product	$F_{remaining}$		[-]	A/P	from applicant or Table 9
Output					
Emission of substance to waste water treatment plant	$E_{local\ water}$		[kg.d ⁻¹]	O	

48. Table 9 lists for various additives the content in rubber products and tyres mostly expressed in parts per 100 rubber parts [phr]. For worst-case calculations the upper range is used. If the content of the additive in the mixture is not specified, then the figure in the overall class (the gray field) can be used. The last column presents the fraction of the additive assumed remaining in the rubber product and therefore not being subject to emissions during processing.

49. These figures should not be seen as a possible recipe. The actual amount used depends on the function of the mixture and can vary within the ranges given. A tyre for example is composed of 10

different rubber mixtures and is made up of 48 wt-% natural and synthetic rubber, 23 wt-% carbon black, 18 wt-% steel, 3 wt-% woven glass fabrics and 8 wt-% additives

[Association of the German Rubber Industry (1999)].

Table 9 Functions and Content of Rubber Additives

Rubber additive	Use in rubber products [phr]	Use in tyres [phr]	$F_{remaining}$
Mastication agents / peptiser	0.1-0.5 wt-% (NR), 1-3 wt-% (SR)	0.5	0.995
Activator	no data	4	
vulcanisation agents	0.25-5 (soft) 25-40 (hard)	up to 2	1.0
sulfur-containing cross-linking agents	2	2	
Vulcanisation accelerator	0.1-2	0.2-2.0	
Accelerator activator	1.5-5	1.3	
sulfur-free cross-linking agents	0.001-1	no data	
coagents for sulfur-free cross-linking agents	0.5-2.0	2.0	
other cross-linking agents	0.001-2.0	0.001-2.0	
vulcanisation retarders	1.5-2	0.3-2	
scorch inhibitors	0.1-1	0.5	
anti ageing and antiflex-cracking agents / antidegradants	0.8	0.8	0.98 (RP) 0.99 (TI)
Antioxidants	0-3	0.25	
Antifatigue agents	1-5	0.2	
Antiozonants	1-7	0.2-1	
light protection agents	0-3	0.2	
anti hydrolysis agents	0.5-3	0,2	
heat protection agents	0.5-3	1	
agents against metal poisoning	0.5-3	0.2	
Deactivators	0.5	0.3	

Rubber additive	Use in rubber products [phr]	Use in tyres [phr]	<i>F</i>_{remaining}
reversion protection agents	0.5-3	no data	
anticyclisation agents	0.5	no data	
Quencher	0.5	no data	
other anti ageing agents	1.5-3.0	no data	
fillers and pigments^{7 8}	Up to 30	up to 40	0.99
Fillers	10-30	40	
Pigments	1-5	No data	
Plasticiser	Up to 20	Up to 3.8	0.95 ⁹
plasticiser, natural	10-20	2.4-3.8	
plasticiser, synthetic	10-20	2.4-3.8	
Processing aids	Up to 15	1-5	0.995
lubricants and flow improvers	5-15	No data	
Tackifier	5-15	No data	
Factices	5-15	No data	
filler activator	5-15	No data	
blowing agents	5-10	3	0.999
bonding agents	1-4	3-4	0.999
Stabiliser	1,5-3	1,5-3	
other agents	0.1-3	0.1-3	0.95

⁷ After formulation, fillers are not removed from the rubber matrix.

⁸ Some fillers act as pigments and vice versa.

⁹ Plasticisers do not enter into a chemical bonding with the rubber; migration to the surface is possible.

Rubber additive	Use in rubber products [phr]	Use in tyres [phr]	<i>F</i>_{remaining}
anticyclisation agents	No data	No data	
replastication agents	No data	No data	
Emulsifier	0.1-0.5	No data

Others	Up to 5	Up to 5	0.95
cleaning agents	No data	No data	
other rubber chemicals	No data	No data	

TI = tyre industry; RP = rubber products

50. An example for a recipe is presented to demonstrate the introduction of the F_{recipe} -factor for information about the composition in phr.

Table 10 Example for a Recipe [Sablowski Datacom 1996]

Compound constituent	Recipe [phr]	Recipe [wt-%]
Synthetic rubber butadiene (SBR)	80.28	43.63
Butadiene rubber (BR)	19.72	10.72
fatty acid	1.97	1.07
Plasticiser	11.97	6.50
Waxes	1.69	0.92
zinc oxide	3.10	1.68
carbon black	60.56	32.91
anti ageing agent	1.69	0.92
Accelerator	1.20	0.65
Sulfur	1.83	0.99
Sum	184.01	99.99

¹⁰ These substances are not a part of the rubber mixture, but will be treated so

4.4 Emission Scenarios for Formulation and Processing to Air and Soil

51. Hardly any monitoring data for air and soil emissions of rubber additives are available. A simple emission scenario based on the A-Tables (emission factors) of the European Union Technical Guidance Document (TGD) [EU 2003] from IC-11 (polymer industry) life cycle phase "polymer use" is presented here. For air emissions, the OECD Emission Scenario on "Additives in the Plastics Industry" (Draft July 2001) may be consulted.

Table 11 Emission Factors [EU 2003, A-Table for IC-11 "Polymer Industry"]

Type of additive	Conditions		Emission factor
Air			F_{air}
	Vapour pressure [Pa]	Boiling point [°C]	
Additives	< 1	< 300 / unknown	0.001
Pigments		> 300	0.0005
Colorants	1-100	< 300 / unknown	0.0025
Fillers		> 300	0.001
Processing aids	>100	< 300 / unknown	0.01
		> 300	0.005
Plasticisers		< 400 / unknown	0.01
		> 400	0.005
Vulcanising agents	<100		0.075
	100-1000		0.15
	1000-10000		0.25
	>10000		0.35
Soil			F_{soil}
Additives			0.0001
Pigments			
Colorants			
Fillers			
Processing aids			0.0005
Vulcanising agents			0.0001

52. The emission rate [kg/d] into air resp. soil is calculated from equation (2) as follows:

$$E_{local\ air} = Q_{prod} \cdot \frac{Q_{additive}}{100 \cdot F_{recipe}} \cdot F_{air} \quad (2)$$

Parameter:

Explanation	Symbol	Value	Unit	Origin	Remarks
Input					
Amount of the product type produced per day	Q_{prod}		[kg.d ⁻¹]	P	see Table 8. If no detailed information is available, the default 55000 kg.d ⁻¹ is used.
Parts of additive introduced per parts of 100 rubber	$Q_{additive}$		wt-% or [phr]	A/P	from applicant or Table 9
Recipe factor	F_{recipe}	2 resp. 1	[--]	A	2, when content is given in phr 1, when content is given in wt-% (see Table 10 Example for a Recipe [Sablowski Datacom 1996])
Emission factor to air resp.	F_{air}		[--]	A/D	from applicant or Table 11
Emission factor to soil	F_{soil}				from applicant or Table 11
Output					
Emission of additive to air resp.	$Elocal_{air}$		[kg.d ⁻¹]	O	
To soil	$Elocal_{soil}$				

4.5 Emission Scenario for Use of Rubber Products by Tyre Abrasion

53. Tyres for motor vehicles cause tyre abrasion that is deposited as particles or dust on streets and roads and on nearby soil [Baumann and Ismeier 1998, p. 307-353]. These particles are exposed to wind transport and weathering so that hydrolysis, leaching, and biodegradation of tyre constituents can take place. Photo transformation by light is unlikely to play a major role on degradation. The following persistent leaching products were identified, when tyres were kept in water (pH 7) or acid rain water (pH 4) for eleven months [Baumann and Ismeier 1998, p. 341] (Table 12).

Table 12 Laboratory Experiments: long-term Leaching Products of Tyres in distilled and acid rain Water, [Baumann and Ismeier 1998, p. 341]

Substance	Abbreviation	Concentration [mg/L]
2-Mercaptobenzothiazol	MBT	< 0.5
Benzothiazole	BT	15 – 1972
2-Methylbenzothiazol	MeBT	< 2
2-Methylthiobenzothiazol	MeSBT	< 2
Aniline		5.9 – 294
Dicyclohexylamine		< 35 – 218
Cyclohexylamine		< 1 – 423

54. These and other additive substances were identified in monitoring studies of street run-off water and urban sediments. These monitoring studies [Baumann and Ismeier 1998; p. 342 - 343; Schmeigel 1995, p. 75; Spies et al. 1987; Kumata et al. 2000] show that tyre abrasion contributes significantly to run-off releases of persistent breakdown products of rubber additives, e.g. benzothiazole and methylated benzothiazole.

55. An approach to calculate the annual regional emission rate [kg/a] of a rubber additive or its breakdown product via tyre abrasion is presented in equation (3).

$$E_{regional_breakdown_product} = Q_{ann_prod} \cdot F_{abrasion} \cdot \frac{MW_{additive}}{MW_{breakdown_product}} \quad (3)$$

Parameter:

Explanation	Symbol	Value	Unit	Origin	Remarks
Input					
Amount of the additive produced per year in defined region	Q_{ann_prod}		[kg.a ⁻¹]	A	The region needs to be defined.
Emission factor for abrasion from tyres	$F_{abrasion}$	0.12	[--]	D	Hartung and Koch 1989 p. 33 Ahlers et al. 1996, p. 73
Molecular weight of additive	$MW_{additive}$		[g.mol ⁻¹]	A	
Molecular weight of breakdown product	$MW_{breakdown_product}$		[g.mol ⁻¹]	A	
Output					
Emission rate of breakdown product (or additive) from tyre abrasion in defined region	$E_{regional}$		[kg.a ⁻¹]	O	The quotient of molecular weights is one, if the additive is considered.

56. The regional emission rate can be the input parameter in any Mackay level III fugacity model (e.g. SimpleBox) for calculating the regional concentrations in surface water and natural soil.

4.6 Emissions from Leachates

57. Considerable amounts of used tyres (about 30%) are disposed off in landfills. In Germany this amount was 135 000 t.a⁻¹ in 1987 [Hartung and Koch 1989, p.81]. Rubber additives and their breakdown products may find their way into leachates of the landfill. Used tyres are used as bumpers in fresh water and marine harbours. Rubber constituents and breakdown products leach to water. The emission rates of such leachate processes are not quantified yet.

5. EXAMPLES OF EMISSION ESTIMATION

5.1 Emissions from Formulation and Processing to Wastewater

A Calculation of the emissions of a plasticiser

Additive in the manufacturing of a tyre; emission occurs during cooling after extrusion (equation 1).

Input Data

Q_{prod}	=	33000	kg.d ⁻¹
$Q_{additive}$	=	3.8	phr
F_{recipe}	=	2	-
$F_{remaining}$	=	0.95	-

Output Data

$E_{local_{water}}$	=	31.35	kg.d ⁻¹
---------------------	---	-------	--------------------

B Calculation of the emissions of an antioxidant

Additive in the manufacturing of a rubber product (equation 1).

Input Data

Q_{prod}	=	22000	kg.d ⁻¹
$Q_{additive}$	=	0.4	phr
F_{recipe}	=	2	-
$F_{remaining}$	=	0.99	-

Output Data

$E_{local_{water}}$	=	0.4	kg.d ⁻¹
---------------------	---	-----	--------------------

C Calculation of the emissions of an anti-ageing agent

Additive in the manufacturing of a truck tyre (equation 1).

Input Data

Q_{prod}	=	14800	kg.d ⁻¹
$Q_{additive}$	=	0.5	wt-%
F_{recipe}	=	1	-
$F_{remaining}$	=	0.99	-

Output Data

$E_{local_{water}}$	=	0.7	kg.d ⁻¹
---------------------	---	-----	--------------------

Example for the determination of the $C_{local_{water}}$ with the data of example B

Additive in the rubber industry. Calculation of PEC_{local} for the aquatic compartment. The EU default values for the waste water treatment plant and the dilution factor are used. Other OECD Member countries may use other default values. Site specific values may also be used.

Chemical: Example:

Amount of the product produced per day
(from Table 8): $Q_{\text{prod}} = 22000 \text{ kg.d}^{-1}$

Parts of additive introduced in
parts of 100 rubber: $Q_{\text{additive}} = 0.4 \text{ phr}$

Recipe factor: $F_{\text{recipe}} = 2$

Fraction of additive remaining in the product: $F_{\text{remaining}} = 0.99$

Fraction of emission directed to water (100% assumed):
(SimpleTreat Model [EU 2003]) $F_{\text{stp_water}} = 100 \%$

Capacity of sewage treatment plant (STP) [EU 2003]: $\text{EFFLUENT}_{\text{stp}} = 2000 \text{ m}^3.\text{d}^{-1}$

Dilution factor [EU 2003]: $\text{DILUTION} = 10$

Factor $(1+K_p*\text{SUSP}_{\text{water}})$ [EU 2003]: $\text{FACTOR} = 1$

Emission per day

$$E_{\text{local_water}} = Q_{\text{prod}} * \frac{Q_{\text{additive}} * (1 - F_{\text{remaining}})}{100 * F_{\text{recipe}}} \quad E_{\text{local_water}} = 0.44 \text{ kg.d}^{-1}$$

Influent concentration

$$C_{\text{local_inf}} = \frac{E_{\text{local_water}}}{\text{EFFLUENT}_{\text{stp}}} \quad C_{\text{local_inf}} = 0.22 \text{ mg.L}^{-1}$$

Effluent concentration

$$C_{\text{local_eff}} = C_{\text{local_inf}} * F_{\text{stp_water}} \quad C_{\text{local_eff}} = 220 \text{ } \mu\text{g. L}^{-1}$$

Concentration in surface water:

$$C_{\text{local_water}} = \frac{C_{\text{local_eff}}}{\text{DILUTION} * \text{FACTOR}} \quad C_{\text{local_water}} = 22 \text{ } \mu\text{g. L}^{-1}$$

$$\text{PEC}_{\text{local_water}} = C_{\text{local_water}} \text{ if } \text{PEC}_{\text{regional_water}} = 0$$

5.2 Emissions from Formulation and Processing to Air resp. Soil

A Calculation of the emissions of a plasticiser

Additive in the manufacturing of a tyre; emission occurs during cooling after extrusion (equation 1).

Input Data	
Q_{prod}	= 33000 kg.d ⁻¹
$Q_{additive}$	= 3.8 Phr
F_{recipe}	= 2 -
F_{air}	= 0.01 -

Output Data	
$E_{local_{air}}$	= 6.27 kg.d ⁻¹

5.3 Emission from Abrasion of Tyres

Example: N-Cyclohexylbenzothiazol-2-sulfenamide (CBS) is degraded to the persistent Benzothiazol (BT). Production of this vulcanisation accelerator in Germany is used.

Input Data	
Q_{ann_prod} (CBS in Germany)	= 2030 t.a ⁻¹
$F_{abrasion}$	= 0.12
$MW_{breakdown_product}$	= 264.50 g.mol ⁻¹
$MW_{additive}$	= 135.18 g.mol ⁻¹
Output Data	
$E_{regional_{breakdown_product}}$	= 124.5 t.a ⁻¹

7. GLOSSARY

Adhesion

The strength of bond between cured rubber surfaces or a cured rubber surface and a non-rubber surface.

Anticoagulant (Natural Rubber Latex)

A substance added to field latex to retard bacterial action, which would otherwise cause rapid coagulation of the latex. *Note:* The word "stabilizer" is often used in place of "anticoagulant" in latex terminology.

Antioxidant

A chemical used to retard deterioration due to heat, light, oxygen, or combinations thereof.

Autoclave

A pressure vessel into which materials or articles can be placed and exposed to steam under pressure. It is commonly used for vulcanisation.

Butyl rubber

Isobutene-isoprene rubber (IIR), synthetic rubber, soft rubber, chlorobutyl and bromobutyl rubber as variants containing halogens with modified properties, high chemical resistance and high resistance to permeation, resistant to ozone and weathering

Calendering

Calendering is a process in tire manufacturing where steel or fabric is coated with rubber. Steel belts, body plies, cap plies and belt edge covers are all produced using the calendering process. Steel or fabric is placed between two large heavy rollers. Rubber is also inserted between the rollers at the top and bottom of the material being coated. As the material moved through the rollers the pressure forces the rubber to permeate and adhere to the steel or fabric.

Compound

A thorough mixture of natural and/or synthetic rubbers with various ingredients designed for each tire part.

Curing

the act of vulcanisation; a description of a definite time and temperature of vulcanisation.

Emulsifier

A surface-active substance used to facilitate the dispersion of an immiscible liquid compounding material in another liquid and to stabilize the emulsion thereby produced.

Extrusion

Extrusion is a process used to manufacture shaped solid rubber. Treads, sidewalls and bead fillers are manufactured using extruders.

Filler

A solid compounding material, usually in finely divided form, which may be added in relatively large proportions to a polymer for technical or economic reasons.

Mastication

To dissolve the rubber in solvents a technology was developed which is capable of softening the rubber by shearing it between two rotors.

Plasticiser

A compounding material used to enhance the deformability of a polymeric compound.

Rubber

Natural rubber or any synthetic, elastomeric material with physical properties similar to those of natural rubber.

Tack

The ability to adhere to itself; a sticky or adhesive quality.

Tackifier

Tackifier resins are processing aids, which help keep rubber components together prior to curing. They are especially useful in synthetic rubber compounds, which have low levels of inherent tack. Tackifiers are commonly incorporated into solvent base, water-base and hot melt adhesives with a base polymer such as natural rubber, styrenic block copolymer, ethylene vinyl acetate, polyethylene homopolymers, and butyl elastomers. The optimum type of elastomer will depend upon the final desired application and performance properties.

Thermoplastic Rubber

Rubber that does not require chemical vulcanisation and will repeatedly soften when heated and stiffen when cooled; and which will exhibit only slight loss of its original characteristics.

Thickener

A substance used to raise or control the viscosity of latex with out the necessity for major changes in the total solids content.

Vulcanisation

An irreversible process during which a rubber compound through a change in its chemical structure (for example, cross-linking) becomes less plastic and more resistant to swelling by organic liquids and elastic properties are conferred, improved, or extended over a greater range of temperature.

8. ABBREVIATIONS

BR	butadiene rubber
CR	poly-2-chlorobutadiene
DIN	German Institute for Standardization
EDTA	ethylene diamine tetraacetate
EPDM	ethylene propylene diene rubber
ESD	Emission Scenario Document
EU	European Union
HF	high frequency
IC	industrial category
IIR	isoprene isobutylene rubber
IR	isoprene rubber
LCM	liquid curing method
Max	Maximum
NBR	acrylonitrile butadiene rubber
NR	Natural rubber
PEC _{local}	Predicted Environmental Concentration at the local stage
phr	parts per hundred rubber
RP	Rubber product
SBR	synthetic butadiene rubber
SR	synthetic rubber
STP	Sewage treatment plant
TGD	Technical Guidance Document of the European Union for Risk Assessment Chemicals and Biocides
TI	Tyre industry
UC	use category
UHF	ultra high frequency
WDK	Association of the German Rubber Industry
