DETERMINANTS OF EARNINGS
IN ESTONIA, LATVIA AND LITHUANIA

This paper investigates the factors that determine wages, using the conventional technique of estimating multivariate earnings functions. The dependent variable is net monthly earnings (in logarithmic form), permitting comparisons with several previous studies in transition countries. Only full-time employees were included in the sample. Three models are used of which two – with and without the variable "occupation" – are almost fully comparable between the three countries; the third includes variables that are not available for all of them.

The wage impact of each explanatory variable is estimated for 1999 and 2000, beginning with human capital-related factors followed by gender, ethnicity, regional effects, unemployment and enterprise characteristics. Data were obtained from labour force surveys (LFS). The actual distribution of full-time employees according to relevant background variables are shown in Tables A3.21 and A3.22.

The text below and most charts express wage ratios and differentials as percentage differences relative to some comparison group. Tables A3.19 and A3.20 show the full results in 2000. Other tables show predicted wages for specific groups (obtained by exponentiation of the dependent variable resulting from the estimated earnings functions).

Human capital: education and work experience

The results suggest that especially higher education has greater impact on wages in the Baltic States than in many other countries, while the opposite holds for age and experience. Work experience and job-related skills acquired under the previous system have apparently lost much of their value, presumably as a result of the transition. On the other hand, the knowledge of foreign languages, computer skills and such characteristics as flexibility, market orientation and ability to learn have become more important. Evidently, young people are on average the most likely to possess these skills and personal characteristics.

---

1 A shorter version of this paper was published as Annex 3 in Labour Market and Social Policies in the Baltic Countries (OECD, 2003). It reports the results of research conducted for the OECD by Mihails Hazans, Eurofaculty and University of Latvia, Raul Eamets, Eurofaculty and University of Tartu, and John Earle, Upjohn Institute for Employment Research, Kalamazoo.

The educational attainment is relatively high in the Baltic States. Of all full-time employees in 2000, the proportion with university education was 25% in Lithuania, 22% in Latvia and 17% in Estonia compared with, for example, 10% in the Slovak Republic, 13% in Poland, 15% in the Czech Republic and 18% in Sweden (Table A3.21). Secondary education had been completed by 60% to 70% of the employees in each Baltic country. Women have on average higher education than men.

In theory, schooling may affect wages 1) by improving productivity, 2) by facilitating access to better-paying enterprises and 3) by facilitating promotion to better-paid occupations. The estimation model that does not control for occupation can be assumed to cover the full effect (Model 1). It suggests that higher (i.e. university) education increased the wage by 66 to 80% compared with basic education. Most of this was due to a premium paid for higher vs. secondary education (of any kind), which alone varied from 44% in Latvia to 59% in Lithuania. The wage premium for secondary vs. basic education was only 13 to 14% in Latvia and Lithuania and 19% in Estonia. If the occupational group is controlled for, the marginal effect of each education type is reduced by approximately one-half, but still highly significant (Models 2 and 3).

University education has greater effect on wages in the Baltic States than in several other transition countries when no control is done for occupation (Figure A3.1). If the occupation is kept constant, however, only Lithuania's higher education appears to have unusually strong effects (Figure A3.2). The returns to secondary education are much lower by any measure in the Baltic States than in most transition countries, and also lower than in more advanced economies. (This is possibly a result of the relatively small proportion of workers with less than secondary education in the Baltic States.)

The wage payoff to a university degree is greater for women than for men in Estonia and Latvia, while in all three countries it is greater for members of the ethnic majorities than for minorities (Figure A3.3). In other words, education is more likely to be effective in reducing the effects of gender segregation than of ethnic segregation. To the extent that persons with higher education work in rural areas, they experience a relatively high wage premium.

---

4 Recent estimates for Ireland suggest considerably higher returns to education, while estimates for Sweden suggest generally much lower returns to education (Barrett et al., 2000, Hansen and Wahlberg, 2000).

5 While the ethnic difference in returns has narrowed since 1998 in Latvia but increased in Estonia, the opposite trends were observed for the gender gap.

6 The returns to education also appear relatively high in the public sector, but this result may be misleading because it does not take account of the greater under-reporting of wages in the private sector. For the same reason, the data may exaggerate the ethnic effect because minority members are over-represented in the private sector in Latvia.

Age can be taken as a proxy for work experience. A typical “western” age-earning profile for men in most education groups is steadily increasing up to about age 50-52, after which it decreases; for women it often peaks somewhat earlier. This pattern is less clear in transition economies, including the Baltic States. In fact, the Baltic age-earnings profiles are almost flat for workers without higher education (apart from the small group of working teenagers; see the Figure A3.4 [after the tables]). To the extent that peaks can be discerned at all, they occur already at age 20-24 or 25-34 in Estonia and Latvia, but in Lithuania at age 35-44 for men and 45-54 for women. The profiles remain similarly flat if they are based not on actual wages (as in Figure A3.4) but on the earnings function of the above Model 1 (Figure A3.5). In this case, the peaks for all education groups tend to occur around age 35 to 40 – much earlier not only than in

7   See e.g. Ehrenberg and Smith (1997), pp. 301 – 303.
8   See Hazans (2002) for a discussion and empirical evidence.
western countries but also than in, for example, the Czech and Slovak Republics. The Estonian male profile stands out as an extreme case, with much steeper slopes before and after the peak than is found either for Estonian women or for men or women in Latvia and Lithuania.

The positive impact of tenure – i.e. length of time in particular jobs, often considered a proxy for firm-specific skills – is also likely to have declined as a result of the high pace of change in transition economies. In 2000, the tenure effect on wages was significant but modest, at 0.5% per additional year of tenure in Estonia and 0.3% in Lithuania (Table A3.19, Model 3). These figures are a little higher than in some Central European countries (Pailhe, 2000). In Estonia, women and Russians were found to benefit more from long tenure than did men and ethnic Estonians.

**Gender**

The average wage for women in Latvia and Lithuania was around 80% of the average for men in 2000 (Table A3.1). This was about the same proportion as in Poland, but more than the 75% reported for Estonia. Even wider wage gaps have been found in, for example, the Czech Republic. Between 1997 and 2000, women tended to reduce their relative disadvantage in Estonia and Lithuania, but only marginally so in Latvia. A closer scrutiny shows that the relative improvement experienced by women in that period mainly concerned white-collar jobs in Lithuania, but mainly blue-collar jobs in Estonia (Table A3.2).

---

9. In the Czech and Slovak Republics, such peaks were found at age 46 to 47 in the private sector and 53 in the public sector based on 1998 data (Juraida, 2001).

10. As elsewhere, however, new entrants to the labour market face a disadvantage in the Baltic countries. Based on Model 3, having worked less than one year reduces the wage by 10 percent in Latvia and 18 percent in Estonia.

11. The Lithuanian data source uses a different definition of tenure: length of time "in the same activity".

12. The Estonian ratio refers to hourly earnings, which shows a smaller gender gap than monthly wages because men have on average longer working time.

Sources: LFS data (for Latvia also earnings survey data) and authors’ calculations.

Notes: Other things, including sector of economic activity being equal.
The gender-related pay gaps are particularly wide in sales and commerce jobs, while they are narrow for semiskilled manual workers (machine operators), for whom there is practically no gender difference at all in Latvia. Wide gaps are often found in occupations and sectors with high average wages (e.g. financial services, not shown in the table) and they mainly concern regions with many high-wage jobs. In Latvia in 1999, women earned on average at least as much as men in six of the poorest districts (Figure A3.6). Indeed, even controlling for all known factors other than the income level, the gender-discrimination effect appears much stronger for medium and high-income groups than for low-income groups (Figure A3.7). This corresponds to previous results for Russia, Uzbekistan, Kazakhstan and Poland, while, on the other hand, gender discrimination has not been found to increase with the income level in the Czech Republic, Ukraine of Yugoslavia.\textsuperscript{13}

Only a limited part of the observed wage gaps can be explained by included factors such as education, economic sector and nine main occupation groups. Baltic women are actually better educated than men on average, but they work more often in low-wage areas. Work experience is not important here because Baltic women have on average at least as long experience and tenure as men (albeit with fewer hours per week). Among the measurable characteristics, a principal factor operating to men's advantage is that wages are higher in some predominantly male activities (transport and communications, construction) than in some predominantly female activities (education, health care), and that public-sector employers, in particular, tend to give men the best-paid jobs (Table A3.20).\textsuperscript{14} Remarkably, the wage premium for professional occupations in Estonia is substantially higher for women than for men (a difference of 19 percentage points, compared to 3 in Latvia and Lithuania).

Weekly working time is on average 1.5 to 2.5 hours shorter for female than male full-time workers (Table A3.21). Although working time was not included in the models used here, it may be considered to explain a limited part the pay difference. Estimates for Latvia (not shown) suggest that including working time in the model would reduce the unexplained wage differential by about one-third.

Otherwise (disregarding working time) the entire gender pay gap in Lithuania, most of it in Estonia and about half of it in Latvia remains unexplained. Apparently, it must be ascribed either to discrimination and occupational segregation within the main groups, or to other unobserved characteristics (Table A3.4, right column).\textsuperscript{15} The results for Lithuania and Estonia are similar to those previously obtained in the US, the UK and Germany, where the apparently unjustified pay gaps are also very considerable. On the other hand, the Latvian situation resembles that in Central European countries, where the known differences between men and women have been found to explain one-third to one-half of the total pay gaps, and where the gaps were substantially smaller within than between occupations.\textsuperscript{16}

The wage gaps that remain after discounting the effects of controlled variables amount to around 10% in Latvia, 14 to 15% in Lithuania and 17 to 21% in Estonia in 2000. (See Table A3.5. The cited figures were obtained using pooled-sample earnings functions.) Controlling for main occupation groups

\textsuperscript{13} Newell and Reilly (2001, Table 4). For Latvia, using household budget survey (HBS) data for 1996, they found no variation in the gender pay gap across the wage distribution, and their estimate of the gap itself was much higher than found here based on LFS data. HBS is less suitable than LFS for estimating earning functions.

\textsuperscript{14} The gender difference in the premium to public-sector work is 19 percentage points in Estonia, 10 in Latvia and 3 in Lithuania. The gender segregation by sector is similar in the three Baltic States.

\textsuperscript{15} Considering hourly rather than monthly pay would narrow the unexplained gap by 2-3 percentage points.

(Model 2 compared with Model 1) reduced the gap by just 1 to 3 percentage points, indicating that if there is occupational segregation it occurs more within than between the main groups.

Wages aside, it has some interest to measure the occupational segregation as such. The results show that it has similar magnitude as in Central Europe (Tables A3.7 and A3.8). The so-called dissimilarity index – expressing the proportion of all women who would need to change occupations to achieve the same occupation structure for women as the actual one for men – can be estimated at 0.35 to 0.41. This is comparable to the Czech Republic, Hungary and Poland. The segregation in the Baltic States is relatively pronounced in the public sector, as in Poland. It has decreased slightly since 1997 in Estonia, where it was highest, and in Lithuania, but not in Latvia.

All told, Latvia appears as one of the least gender-discriminatory economies, comparable to Hungary and Slovakia, while the wage gaps observed in Lithuania are only marginally wider. Moreover, the occupational element of segregation appears unusually small in Lithuania. On the other hand, all models used here support the result that Estonian women suffer the greatest wage disadvantage in the Baltic States (Tables A3.5 and A3.6). But even wider gender gaps have been found in Bulgaria and Central Asia – and in English-speaking countries.

Ethnicity

According to LFS in 2000, the average wage differential between the Baltic majority populations and ethnic minorities was 16% in Estonia and 9% in Latvia and Lithuania. (LFS respondents' ethnicity was self-reported. Except for Estonia, it was not possible to connect it with information about language skills, which probably play a role.) The predominantly Russian minorities of the two northern countries hardly differed from the respective majorities in terms of education (apart from the languages). But in Lithuania's minorities – which include a significant rural element, often Polish – the proportion with university education was only 16% compared with 26% for ethnic Lithuanians.

Occupational segregation also appears strongest in Lithuania, while it is weakest in Latvia. (Table A3.7 shows an ethnic dissimilarity index for occupations of 0.29 in Lithuania – almost as high as for genders.) Nevertheless, the pattern of occupational segregation is similar in all three countries, with minorities over-represented among manual workers and under-represented among senior officials, managers and professionals, in Lithuania also among technicians.

By contrast, the segregation by economic sector is strongest in Estonia and weakest in Lithuania (Table A3.7 shows sectoral dissimilarity indices: 0.26 for Estonia, 0.14 for Lithuania). But here the impact on wages can go in both directions because the minorities are not only concentrated in low-wage sectors (Table A3.9, more detail in Table A3.21). Only in Latvia does the public sector employ relatively few minority members.\(^\text{17}\) Last but not least, in all three countries, relatively high proportions of the minorities have the advantage of working in the capital cities, where wages tend to be high.

Only in Lithuania can a substantial part of the gross wage differential be explained by measurable employee characteristics (Table 3.10). Occupation alone (nine main groups) explains pay gaps of 4.2% in Estonia, 3.4% in Lithuania and 2% in Latvia. In other words, occupational segregation explains 35 and 45% of the observed gross wage differential in each country. In Estonia and Latvia, however, the wage effects of occupational segregation is largely offset by other known factors that actually seem to favour minorities, including sector, region and – in Estonia – the size of enterprises. Some 55% of all non-Estonian employees compared with 30% of the Estonian employees worked in firms with over 50 workers.

\(^\text{17}\) Among employees, about 35% of the non-Latvians and 49% of the Latvians work in the public sector.
Because big enterprises pay relatively high wages, controlling for firm size increases the unexplained ethnic wage gap by 2 percentage points in Estonia (Model 3).\footnote{Wages and firm size are positively correlated both in raw data (Chapter 8) and in \textit{ceteris paribus} equations (Table A3.19, Model 3).} In Lithuania, by contrast, there is no such effect because Lithuanian and minority employees have almost the same distributions by firm size.

As with the gender-wage gap discussed above, a residual part of the ethnic wage gap must be ascribed to unobserved characteristics (Tables A3.10 and A3.11). Although these probably include language skills, it has often been assumed in other countries that such residuals measure discrimination. Using Model 1 (to include the wage effect of occupational segregation) the apparently unjustified ethnic wage gaps were about 7% in Latvia and Lithuania in 2000, or approximately equal to the ones estimated for Black vs. White citizens in the United States (Table A3.12). The corresponding gap in Estonia was much wider: 18%. Comparison with a previous study in Estonia suggests that it has increased by about 4 percentage points since 1994.\footnote{Kroncke and Smith (1999) used a model equivalent to Model 1 here, with weighted Estonian and non-Estonian earnings functions. The analysis for Latvia in Chase (2001) is not directly comparable because it lacked sectoral dummies and used a different data source (household budget surveys instead of LFS), but the results are similar to those found here.}

A closer scrutiny shows that the ethnic wage discrimination in Lithuania is stronger for men than for women and that it mainly concerns low-wage groups (Figures A3.7 and A3.8).\footnote{The results about correlations with income levels rely on quantile regressions, also used by Reilly (1999) and Newell and Reilly (2001).} In Latvia, by contrast, it is strongest for high-wage groups. In Estonia it is stronger for urban than rural workers, and stronger in the private sector than in the public sector. Cyclical factors appear to play a role, as shown for example by a temporarily worse situation for women in Estonia and Latvia in 1998 and 1999.

\textit{Regional effects and commuting}

As mentioned already, jobs in the capital cities tend to be relatively well paid. Contrary to the results in \textit{Unemployment Risk Factors in Estonia, Latvia and Lithuania} (another OECD web paper) concerning unemployment – which showed that the lower unemployment risk in the capitals could be explained by such factors as job type, education and economic sector – the pay difference in favour of the capitals remains significant even when those factors are controlled (Table A3.13). The same applies to varying degrees for the districts surrounding the capitals, for other major cities (Kaunas and Klaipeda in Lithuania and Ventspils in Latvia) and for smaller cities compared with rural areas. Inclusion of dummies for these locations in the earnings functions generally has highly significant effects.

Compared with an employee working in a small city in 2000, an otherwise similar employee in a rural part of any Baltic country earned 8 to 9% less. Employees working in the capitals earned 21 to 23% more than those in small cities in Estonia and Latvia – similar to, for example, the difference between Warsaw and small cities in Poland in 1998 (Newell, 2001, Table 9). But the employees in Vilnius earned only 12% more than those in small Lithuanian cities.
Figure A3.8 Ethnic wage ratio *ceteris paribus*: minority vs. majority employees

*Note:* Other factors (including economic sector) are kept constant. All shown ratios except for the rural population in Estonia (1999) and Latvia (2000) are significantly different from 1 (at least at 0.1, mostly at 0.001 level).

*Sources:* LFS, for Latvia also enterprise census data; and authors’ calculations.

However, in Estonia and Latvia, the impact of location looks much smaller if it is measured by *residence* rather than *workplace*. This narrows the *ceteris paribus* wage gaps between the capitals and rural areas by 16 percentage points in Estonia and 11 percentage points in Latvia, and between the capitals and other cities by 9 percentage points in both countries. In Lithuania, on the other hand, there is little difference between the effects of workplace and residence, suggesting that commuting is less important than in the two northern countries.

In Latvia, every 10 km of distance between a job location and Riga decreases the *ceteris paribus* wage by 1.1% – except if the job is in Ventspils (Table A3.14, which shows results for five alternative specifications of the earnings function. Only the Latvian data allow such estimations.) The effect of the distance from Riga is only slightly reduced if one controls for the local unemployment rate. Every 10
kilometers of *commuting* increased the wage by 2.5 to 3%. The positive effect of commuting appears to have been greater in the crisis year of 1999.

**The local unemployment rate**

The relationship between wages and local unemployment can be measured as an elasticity, typically found to be about -0.1 in OECD countries. Based on the data used here combined with unemployment at the job locations, the wage elasticity in Estonia was -0.24 in 1999 and -0.15 in 2000, in Latvia -0.11 in 1999 and -0.05 in 2000. In Lithuania, by contrast, there was practically no connection between local unemployment and wages.

Expressed differently, the *ceteris paribus* wage differential associated with a 1 percentage point difference in the local unemployment rate in Estonia was -2.0 in 1999 and -1.1 in 2000, in Latvia -1.2 in 1999 and -0.5 in 2000 (Table A3.15). Probably, the higher figures in 1999 reflected the impact of the Russian crisis, which likely influenced both earnings and employment in the localities concerned. In 2000, by contrast, such regionally concentrated developments appear to have been less decisive for earnings.

Wages of professionals and technicians are less sensitive to local conditions than those of other groups. In Latvia, the observation that working or living in Latgale results in a wage cut of 11 to 14% compared to small cities elsewhere (cf. Table A3.14) is consistent with the relatively high unemployment there. A further result concerning Latvia is that the predicted wage is reduced by 11% if a worker has been registered as unemployed in the past.

**Ownership, economic sectors and firm size**

Wage statistics based on enterprise surveys have recently showed around 20% higher wages in the *public sector* than in the private sector, although the difference appears to have disappeared in Estonia in 2000 (Table A3.16). These results must be used with great caution for several reasons, including a likely under-reporting of wages paid informally (in "envelopes"), especially in the private sector.

---

21 The results vary within this range depending on the inclusion or exclusion of occupation, Latgale, distance from living place to Riga, and local unemployment rate. Significance at least at the 0.001 level.

22 Elasticities of around -0.1 have been found in for example the US, the UK, Italy, Switzerland, Norway, Canada and some developing countries. Somewhat different observations have concerned Australia (--0.19) and Korea (--0.04). See Blanchflower and Oswald (1996) and Blanchflower (2001). The latter paper (using data from the early or mid-1990s, with fewer control variables) reports a similar result for eastern Germany, but higher elasticities (--0.18 to --0.36) for Poland, Bulgaria, Hungary, Russia, and Estonia (--0.3 in 1995) and Latvia (--0.5 in 1995-96, using a smaller sample, less disaggregated regions and a less accurate unemployment measure than this study), and almost no elasticity in Slovenia. Blanchflower's prediction that these elasticities are likely to fall in the late transition seems consistent with the results of present study.

23 ILO unemployment for Estonia, registered unemployment for Latvia

24 Adamaite (2001) studied the wage curve in Latvia using regional average wages, but with no controls for personal characteristics.

25 In Estonia, the changing wage relationship between public and private sectors appears to result from an increase of municipal employment in the public sector, and, in the private sector, a growth of relatively high-paying foreign-owned enterprises. Cf. NBB results, quoted elsewhere in this report.
However, LFS data also point to the existence of a public-sector wage premium. The estimates made here indicate a *ceteris paribus* wage gap of 5 to 10% in all three countries, depending on which of the background factors are controlled for.26

Similarly, the often very wide gaps between average wages in different *economic sectors*, as found in official statistics, are largely "explained" by various background factors, notably occupation, education and job location. (See Table A3.17, which – like the preceding table – compares average wages according to enterprise surveys with *ceteris paribus* wages, predicted from LFS data.) Nevertheless, the ranking of most of the sectors remains similar. Notable exceptions are Public administration, for which the reported relative wages are much higher and than they would have been if the observed background factors were equal, and Hotels and restaurants for which the opposite holds.

*Firm size*, finally, accounted for a differential in *ceteris paribus* wages of approximately 10% in Latvia and Lithuania and as much as 18% in Estonia, comparing firms with under 10 employees with those with over 50 employees (Table A3.18). This size effect of the same order as in Poland.27

26 While LFS may not under-report of "envelope" wages as much as enterprise surveys, they probably under-represent high-income earners, found especially in the private sector.

27 Estimates for Poland suggest a *ceteris paribus* pay disadvantage of 10 to 14% for firms with under 20 employees compared with those with over 100 employees.

<td>Latvia</td>
<td>19</td>
<td>7</td>
<td>10</td>
</tr>
<tr>
<td>Lithuania</td>
<td>14</td>
<td>-1</td>
<td>0</td>
</tr>
</tbody>
</table>

Notes: Wage differentials were calculated, following a conventional decomposition method, as exp(d)−1, where d is the difference between mean log net monthly wages of males and females. Note that the ratios in Table A3.1, in contrast, refer to (arithmetic) mean wages. Outliers and influential observations were removed from the samples when estimating earning functions. The explained gender pay gap, sometimes called the productivity differential, refers to (geometric) mean predicted wages of males and females, using earnings functions estimated over pooled sample.

* Economic sector is controlled for.

Sources: Calculations based on LFS, for LV also enterprise census data.

</tbody>
</table>

**Notes:** Monthly wages except for Poland (1996), Bulgaria, Yugoslavia, Russia and Ukraine, where hourly wages were used. Monthly wages exaggerate discrimination if men work longer hours. Brainerd (2000) and Newell and Reilly (2001) show that the evolution of the gender gap has been slow in most transition countries, so the comparisons with 1995-96 and earlier should have some relevance.

Controls in Model 1: education, age, ethnicity, sector of economic activity, ownership, region.
Controls in Model 2: same as Model 1 plus occupation.
Controls in Model 3: same as Model 2 plus tenure and firm size (EE, LT), new entrant (EE, LV).
\(^a\) Earnings function assuming non-discriminatory wages. M = male, F = female, P = pooled.
\(^b\) Only for EE, LV, LT.

**Sources:** EE, LV, LT: LFS data and authors’ calculations. PL, CZ, SK, HU with pooled base: Pailhê (2000); PL, CZ, SK, HU, BG, YU, RU, UA, UZ with male and female base quoted from Newell and Reilly (2001).

**Notes.** Dependent variable: logarithm of monthly earnings. Method: Survey linear regression with White’s heteroskedastic standard errors. Variables significant at 0.1 (respectively, 0.01, 0.001) level are denoted by *, **, ***. Outliers and influential observations removed for each model.

- Marital status variables for Latvia and Estonia and Regional unemployment rate for Lithuania are not significant; controlling for them does not change the results substantially but makes the estimates less accurate.
- New entrant=less than one year's experience.
- Number of years with current employer (Estonia); number of years with current employer or in current activity (Lithuania).
- These occupations were merged with corporate managers in Estonia.
- Too few respondents in Fishing for Latvia and Lithuania.
- Too few respondents in Mining for Latvia.

**Sources:** Calculations based on LFS (January for Estonia, May for Latvia and Lithuania) and (in Latvia) wage imputation from the survey on occupations.
