## VI. ASSET PRICE CYCLES , “ONE-OFF” FACTORS AND STRUCTURAL BUDGET BALANCES

### Introduction

#### *Asset cycles significantly affect structural budget balances*

This chapter considers two factors which may cause cyclically-adjusted budget balances to give a misleading picture of underlying fiscal trends. It first explores the implications of recent large asset-market related fluctuations in government revenues for the measurement of structural budget balances. And second, it reviews the impact of the increased recourse to stopgap “one-off” measures to control deficits. Traditional methods of calculating the cyclical components of budget balances correct government receipts and transfers for the cycle in economic activity, but do not adjust revenues for cycles in asset prices. Fluctuations in tax receipts related to asset prices may be seen as permanent where the fundamentals determining asset prices (such as profits, productivity growth and risk premia) seem to have undergone a structural change. Where they have not, the cyclically-adjusted balance may then give too favourable a “structural” picture by not recognising the temporary nature of tax buoyancy arising from higher asset prices (and the converse). “One-off” measures may also undermine the accuracy of the cyclically-adjusted measure as a structural budget indicator, requiring correction -- as is the OECD procedure with respect to the proceeds of auctions of mobile phone licences, for example.

The chapter begins by reviewing recent developments in cyclically-adjusted budget balances, identifying the sources of revenue and expenditure change in the two major fiscal phases which have characterised OECD-area fiscal policy over the past decade: the period of fiscal consolidation from 1993 to 2000 and the subsequent relaxation during the 2001 to 2003 period. For a small set of OECD economies, “unwarranted” shifts in cyclically-adjusted fiscal stance are then identified, relative to a benchmark based on conventional elasticity estimates and announced tax policy changes. In the subsequent section, which covers a somewhat wider set of countries,<sup>1</sup> the impact of the asset price cycle on individual tax

sources is assessed with particular emphasis on capital gains taxes. The final section looks at the impact of exceptional (“one-off”) sources of budget change.

***Revenue buoyancy increased temporarily in the late 1990s...***

The results confirm that since the late 1990s revenues have been more buoyant than would have been warranted by the registered rate of nominal output growth and the impact of tax measures. The study suggests that from 1995 to 2000 the average contribution of “unwarranted” revenues to year-to-year changes in cyclically-adjusted budget positions ranged from negligible to around ½ per cent of GDP, the main countries affected being the United States, the United Kingdom, France and some Nordic countries. On average, this revenue “excess” would seem to have been of the same magnitude as if output growth had been underestimated by around ½ per cent per annum over the period. Conversely, the subsequent decline in tax receipts has been sharper than could be warranted by output movements and tax measures, and in some cases the decline explains a significant part of the shift in cyclically-adjusted balances.

***... and budget management may have been compromised***

The “excess” revenue at the cyclical peak in 2000 was important enough, in some instances, to have led to misjudgments about the level of structural budget balances of the order of 1½ to 3 percentage points of GDP. Over-statements of the strength of the structural budget position, due to overconfidence about the permanence of tax receipts (coupled with over-optimistic growth projections) may have led governments to reduce taxes or defer spending cuts to an extent which compromised subsequent budget management. In the late 1990s, the momentum of fiscal adjustment was weakened and in a number of countries the opportunity was lost to bring budgets into surplus or at least close to balance during a period of relatively buoyant growth.

***Asset-related swings in tax receipts have been a major factor...***

Assets-related swings in revenues appear to have been a major factor in explaining “excess” revenues. And for those countries most affected, the quality of the cyclically-adjusted fiscal balance as a “structural” budget indicator could, in principle, be improved by making additional *ex post* corrections for fiscal movements linked to asset prices cycles. The adjustment explored below produces results which are, on occasions, quite different from the conventional cyclically-adjusted indicators. Nonetheless, *ex ante* difficulties in distinguishing temporary asset price movements from permanent ones make forward-looking adjustments difficult, while uneven fiscal data coverage between countries preclude an internationally consistent reassessment of the cyclical adjustment method.<sup>2</sup> Differences in tax regime also imply that the importance of making such an adjustment varies from one country to another.

---

2. Other sources of bias in assessing structural budget positions include measurement errors linked to the computation of output gaps, to fluctuations in tax elasticities and to the composition of income and demand. See Cotis *et al.* (2003), Gonzales-Minguez *et al.* (2003), Bouthevillain *et al.* (2001) and the Appendix.

*...calling for the identification of temporary and irregular factors*

Efforts are, nevertheless, being made at the national level to improve data and structural position measurement in the United States, France, the United Kingdom and several European countries, which involve the identification of temporary revenue swings.<sup>3</sup> These include also the effects of “one-off” factors, of which the chapter provides a non-exhaustive list. This is an area where further classification and cross-country estimation are needed. Adjusting for asset price effects and “one-off” measures should help to avoid the mistakes of overstating structural budget balances apparent during the past upturn.

### **Fiscal positions in OECD countries**

#### *Revenue and expenditure components of budget stance*

*Fiscal positions improved during the second half of the 1990s...*

Fiscal positions improved remarkably during the 1995-2000 upturn, but have deteriorated sharply in the course of the downturn (Table VI.1).<sup>4</sup> The associated swings in the cyclically-adjusted deficit amounted to close to 3 per cent of potential GDP for the OECD area as a whole during the consolidation phase, followed by a deterioration of just over 2 per cent in the course of 2001-03. During the upturn, the nature and extent of discretionary action behind these shifts varied:

- In the United States, higher tax receipts made a contribution equal to that of expenditure restraint to the improvement in the cyclically-adjusted balance up to 2000. The United Kingdom, Spain, Norway and Australia experienced a similar pattern of fiscal “forces acting”, higher effective tax rates and spending restraint both being used to consolidate.
- In France and Germany, the consolidation phase relied almost exclusively on tax receipts, current spending keeping pace with GDP growth, or nearly so, while in Portugal “excess” revenue buoyancy was almost used up in faster expenditure growth.
- For Italy, Canada and most of the smaller euro-area economies, the consolidation process of the 1990s was based heavily on expenditure restraint, revenue growth being maintained quite close to that of GDP.

---

3. For example, Kranendonk (2003) has recommended that the European Commission take account of the country-specific lag between the output gap and the cyclical component of the budget balance. This is relevant when taxes and unemployment benefits react with some delay to changes in economic growth.

4. The sources of the tax revenue data used in this chapter are both from OECD National Accounts and OECD Revenue Statistics. They are not fully comparable due to a variety of general and country-specific factors.

Such revenues are recorded as negative capital outlays for these countries.

*a)* Data for the cyclically-adjusted balance refer to mainland economy only, i.e. excluding revenues from the petroleum activities.

### ***... but have since deteriorated unexpectedly***

In a majority of OECD countries, a prominent and widespread feature of the fiscal deterioration is the extent to which revenues have fallen beyond what might normally have been expected from the cyclical downturn. The United States has seen a particularly abrupt revenue shortfall, but there have also been substantial negative swings in Canada, France, the Netherlands, the United Kingdom and in some of the Nordic countries. In some economies, notably Belgium, Italy and Spain cyclically-adjusted balances have stabilised or even continued to improve slightly. However, this has in some cases been the result of measures which have only a “one-off”, temporary effect.

*Discretionary versus unplanned revenue shifts****Revenue buoyancy has been abnormal...***

Table VI.2 provides an *ex post* measure of the extent to which movements in tax ratios have reflected autonomous (exogenous) forces not captured in traditional revenue-projection processes. Deviations from normal revenue behaviour are defined as “residual” changes in tax receipts, which cannot be explained by revenue growth deriving from the actual growth of GDP (measured according to conventional elasticities<sup>5</sup>) or identifiable discretionary fiscal policy measures<sup>6</sup> (see Appendix). Unfortunately, time series data on discretionary fiscal actions is not widely available, so this stage of the analysis was limited to three countries: the United States, France and Canada.

***... for household income taxes...***

Using this methodology, it emerges that the United States experienced autonomous increases in revenues from direct taxes on households (*i.e.* over and above what could have been expected from cyclical and announced discretionary factors) amounting to almost ½ per cent of potential GDP *per annum* in the late 1990s. This rose to over 1 per cent in 2000, but was followed, in 2002, by an undershoot of more than ¾ per cent of GDP. In France and Canada, the growth of direct household tax revenue consistently overshot projected values by an average of ½ and ¼ per cent of potential GDP *per annum* during the 1995-2000 period respectively, before returning closer to the predicted value during the downturn.<sup>7</sup>

***... but not so for corporation taxes***

On the other hand, corporate income tax revenues have been quite close to the values which would have been predicted given actual profit outturns, throughout the whole cycle, with a slight tendency to over-prediction. This may be indicative of the fact that movements in profits were less affected than personal incomes by asset price movements. Indeed, earnings/price ratios were falling during much of the stock market boom.

- 
5. See van den Noord (2000). The tax elasticities are based on OECD estimates and are assumed to have been constant over the observation period.
  6. Estimates of discretionary policy change relate to federal government for Canada and to central governments for France and the United States. They are based on their officially projected impact provided at the time of enactment. These estimates have not been updated for later information such as actual incomes and taxpayer responses and thus represent only an approximation of the magnitude of the true discretionary policy changes. Part of the “unexplained” revenue may thus reflect a mis-estimation of discretionary measures. In most cases, however, the extent of the bias will be quite small, especially for income taxes where the effects of changing tax schedules and allowances can be quite accurately predicted.
  7. The results for the United States and for Canada are in line with other studies. See Congressional Budget Office (2002) for the United States, King and McMorran (2002) and Kennedy and King (2003) for Canada.

*In aggregate, tax windfalls and shortfalls have been significant...*

Aggregating both household and corporate taxes, the total autonomous direct tax growth windfall from one year to the next for the United States averaged ¼ per cent of potential GDP during the 1990s upturn, and the corresponding shortfall averaged ½ per cent of potential GDP in the subsequent downturn. France and Canada experienced a slightly larger average positive error in the upturn (close to ½ per cent of potential GDP) but appear to have been less affected in the downturn.

*... and have been correlated with asset price movements*

Since the calculations are based on actual outturns for GDP and the output gap, the implications are that exogenous factors were acting to push up the tax base, or that the tax elasticities changed. Figure VI.1 suggests that the source of the unexplained residuals might be traced, at least in part, to asset price changes, as tax windfalls/shortfalls have been correlated to some extent with the asset price cycle.

### *Implications for the interpretation of the fiscal policy stance*

#### *Measurement implications are important...*

Cyclical adjustment traditionally serves two major roles: as a measurement of “discretionary” fiscal stance and as an instrument of medium-term budget planning, based on various normative views about what the structural deficit should be for the budget to be sustainable.<sup>8</sup> The first focuses on changes in the cyclically-adjusted balance, the second on its level. The autonomous revenue shifts have implications for both interpretations.

#### *... relating to discretionary policy responses...*

In the United States, announced discretionary policy measures have generally amplified autonomous (residual) revenue shifts (Table VI.2), adding to receipts in the upturn, and lowering revenues in the downturn due to the tax cuts legislated in mid-2001 and to the stimulus package passed in March 2002. By contrast, in France, discretionary tax cuts offset more than a half of the autonomous rise in revenues during the upswing -- a pro-cyclical response. The offset was more partial in Canada.

A similar picture emerges in Figure VI.2, which compares changes in the traditional cyclically-adjusted fiscal stance with cyclically-adjusted measures which exclude autonomous revenue shifts:

- For the United States, fiscal policy appears less deliberately restrictive between 1995 and 2000 and the subsequent fiscal loosening appears less important than calculated with the traditional fiscal indicator.
- For France, fiscal policy in 1999 appears less restrictive and the subsequent fiscal loosening between 2000 and 2002 is smaller than calculated with the traditional fiscal indicator, but to a lesser extent than for the United States.
- In Canada, the fiscal expansion in the late 1990s and the following consolidation period are roughly of similar magnitude when calculated with both indicators. However, the year-to-year pattern is different.

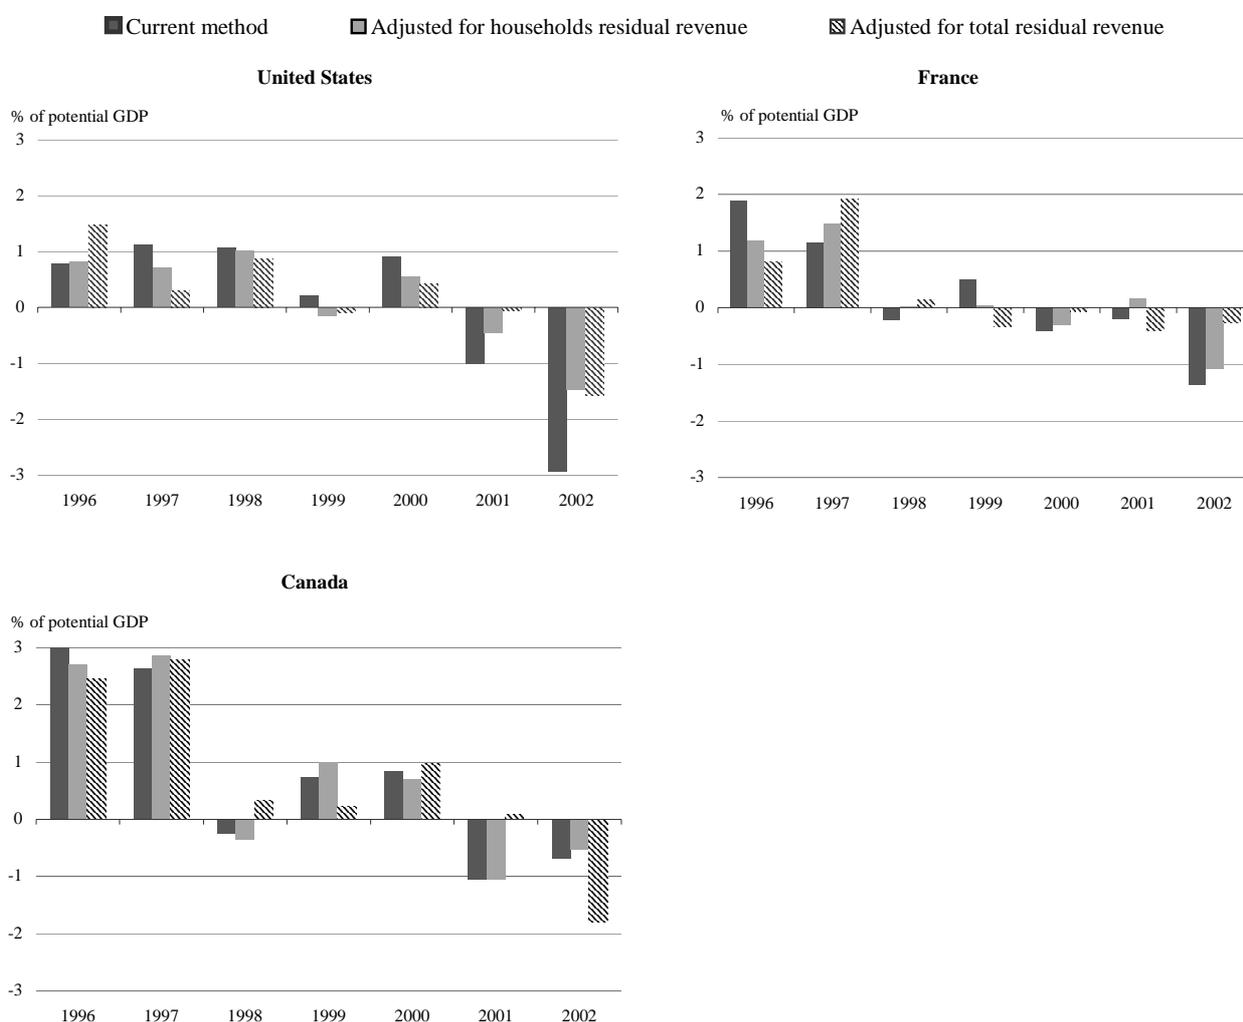

#### *... and structural budget stance*

Perhaps the most important implication is for the calculation of the underlying *level* of the structural budget balance. In that case, it is the cumulative effect of the autonomous budget changes that matters (penultimate set of columns of Table VI.2). During the upturn, if the extra

revenues had been treated as wholly cyclical, for the United States the “structural” surplus of near to 1¼ per cent of potential GDP in 2000 would have been reduced to a deficit of close to ¼ per cent of potential GDP. The French structural deficit of close to 1¾ per cent of potential GDP would actually have been negative to the amount of about 4¼ per cent. These calculations evidently presuppose that in the base year, 1994, the revenues associated with asset prices and similar effects were at a “normal” level.

### The effects of asset-price cycles on different revenue components

***Taxes on assets may be the source of autonomous revenue fluctuation***

This section looks at the impact of individual sources of tax revenue related to asset markets and their role as a source of autonomous fluctuations.<sup>9</sup> There are several avenues, of which the principal one investigated is capital gains taxes. Using a statistical approach, an attempt is made to adjust structural balances for the non-structural element of capital gains tax. The sample of countries analysed in this case is somewhat wider than in the previous section.

### *Capital gains tax receipts have fluctuated*

***Surges in capital gains tax revenues have been significant...***

The boom in stock markets in the late 1990s led to an extraordinary increase in capital gains tax collections (Figure VI.3). In the United States, taxes on household capital gains doubled between 1995 and 2000, reaching slightly over 1 per cent of GDP before falling to around ½ per cent of GDP in 2003. In Finland, taxes on capital gains rose from ½ per cent of GDP in 1998 to 1½ per cent of GDP in 2000 before falling back to the 1998 level in 2002. In Sweden, capital gains taxes also recorded large swings, from ¾ per cent of GDP in 1995 to 1¾ per cent of GDP in 2000 and back to ¾ per cent of GDP in 2002. Comparable fluctuations, although smaller, were recorded in the United Kingdom. In France, Italy and Australia, large increases were also registered, but data including the subsequent falls are not yet available. By contrast, in Japan, capital gains revenues have been on a declining trend throughout the 1990s. It is capital gains realisations that are taxed rather than capital gains accruals, and movements in realisations tend to lag movements in asset prices.<sup>10</sup>

***... but they are not necessarily correlated with output cycles***

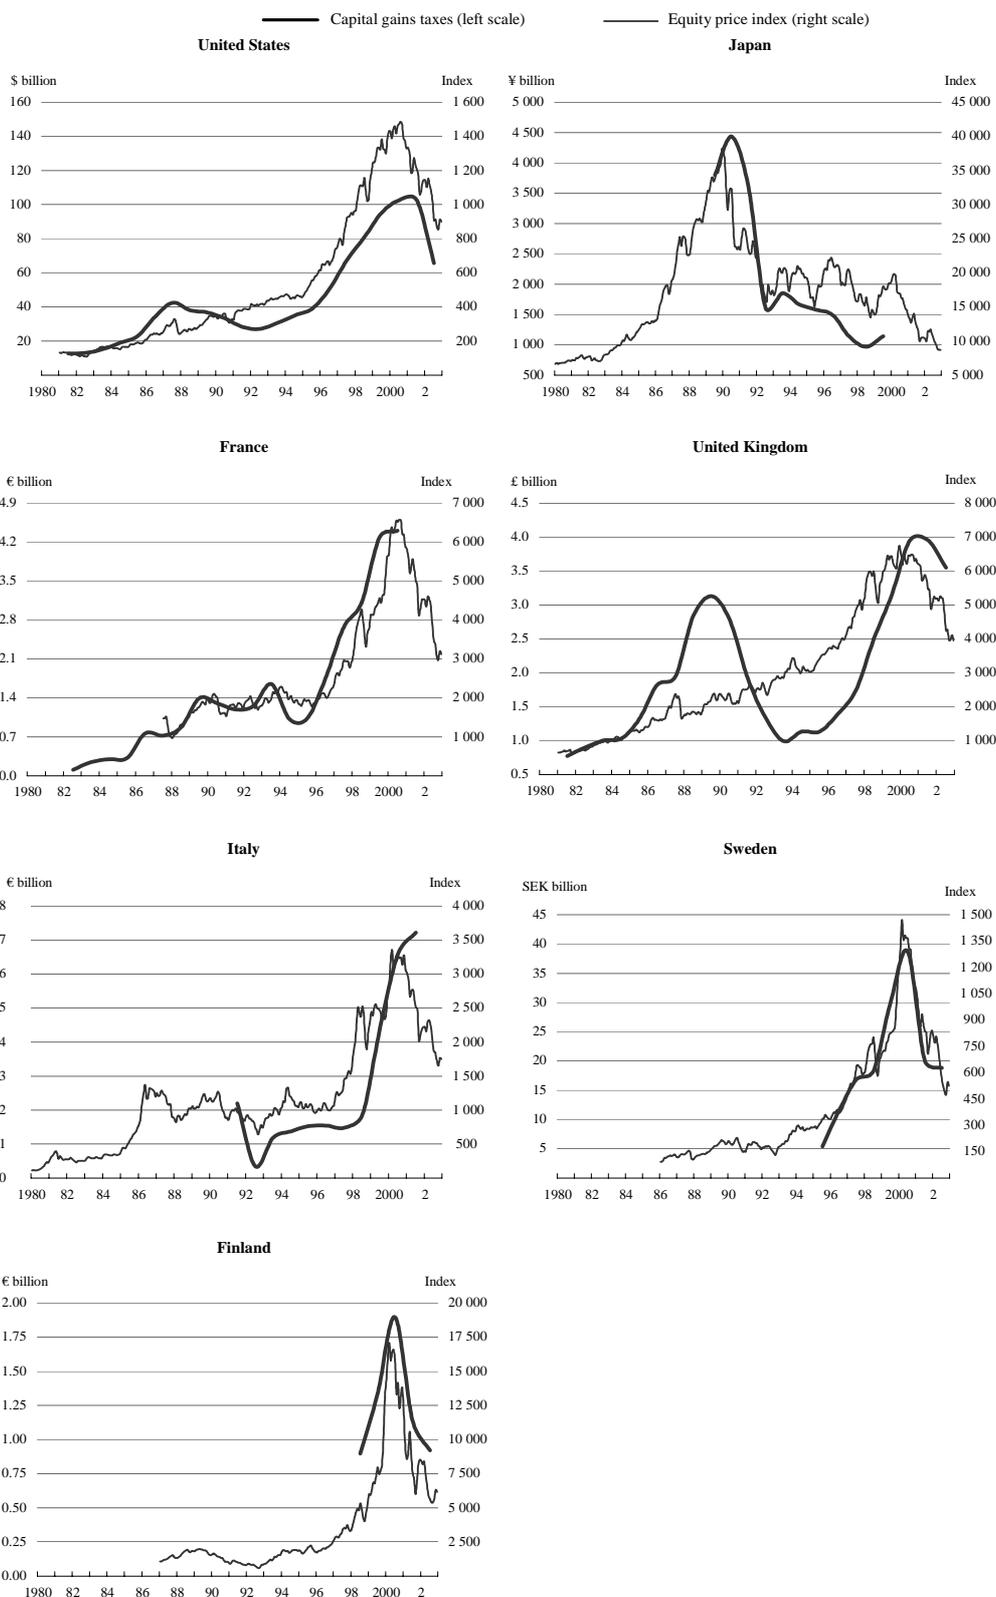

The output and asset price cycles seem to have been only partly correlated since the early 1990s, at least as far as equity prices are concerned. The capital gains component of the tax base has thus not varied systematically with the cycle. Moreover, during periods of structural change, there will always be difficulties in separating permanent from temporary determinants of asset prices, and different tax treatment means that uncertainty as to capital gains tax revenue elasticities is rather large. Altering the cyclically-adjusted process to allow for variations in capital gains relative to other income would thus seem to be a relatively unpromising way forward.

---

9 . See also Eschenbach and Schuknecht (2002a).

10 . In both rising and falling markets, large amounts of accrued gains are available for realisation and taxation, awaiting taxpayers' decisions as to the selling of their assets. Indeed, after a bull market such as that of the 1990s, a sizeable amount of accrued gains remains to be realised and equity sales in a falling market can still result in taxable gains, albeit reduced. In the United States for example, realisations in 2000 increased by 16 per cent despite the fall in the Standard & Poor's 500 stock price index during that year (Congressional Budget Office, 2002).

### *Adjusting structural balances for capital gains revenue*

#### *Adjustment may be made for capital gains tax revenues...*

However, a partial correction for the asset price cycle can be made by separating capital gains tax revenues into trend and cyclical components.<sup>11</sup> At the limit, such revenues could be treated in the same way as debt interest payments, which are netted out to obtain a cyclically-adjusted primary balance, which is regularly published by the OECD.<sup>12</sup> But alternatively, where data permit, the adjustment can be achieved using a statistical approach, the underlying (structural) trend in capital gains revenue being isolated with the Hodrick-Prescott (HP) filter method.<sup>13</sup> The trend component can be interpreted as structural revenue, while the deviations from trend are attributable to the asset price cycle.

#### *... by including only trend receipts...*

Figure VI.4, panel A compares the traditional cyclically-adjusted balances with HP filtered capital gains tax revenues. The order of magnitude is smaller than the “excess” revenue adjustment implied by Table VI.2 -- about one half for the United States and one fifth for France between 1997 and 2000 -- reflecting the fact that capital gains tax revenues are only a part of the overall story. However, the additional correction would still have led to a reappraisal in the structural budget stance at the peak of the cycle. In the US case, the cyclically-adjusted budget would have been only marginally in surplus in 2000, while the UK budget would have been reduced by ¼ per cent of GDP between 1998 and 2000. In France, the deficit would have been only marginally lower over the same period. In the recent downturn, US fiscal policy appears to have been less deliberately expansionary than calculated with the traditional fiscal indicator. There is less of an effect in France and the United Kingdom.

#### *... or by excluding all capital gains tax receipts*

Figure VI.4, panel B, illustrates the effect of directly excluding capital gains tax revenues from the cyclically-adjusted balance in several OECD economies where data did not permit a statistical adjustment. With this methodology, the overall pattern of fiscal consolidation still holds during the late 1990s, given the level shift effect of excluding all the capital gains tax revenues. Nevertheless, losses of revenue after the 2000 peak are substantial for Sweden and Finland, where the effects are largest. The

- 
- 11 . The taxation of capital gains varies considerably among OECD countries. Such taxation may apply only in specified cases such as the sale of real estate and may be imposed by adding gains to ordinary income or *via* special taxes. Moreover, it is generally realisations that are taxed and these are not contemporaneous with movements in asset prices. See Girouard and Price (2004).
  - 12 . The cyclically-adjusted measure suffers from conceptual deficiencies with respect to the interpretation of interest payments and the impact of inflation. In a high-inflation environment it may be necessary to adjust the deficit for the “inflation tax” on government debt holders. See Price and Muller (1984).
  - 13 . See Richardson *et al.* (2000) for a critical discussion of filtering methods. For the purpose of filtering the time series, data have been extended to 2010 in order to mitigate potential bias at the end point. The extension of the data set for the United States comes from the Congressional Budget Office medium-term projections, while those for the United Kingdom have been constructed by replicating the growth path of the 1977 to 1995 period. For France, it has been assumed that revenues from the capital gains tax revert rapidly to their long-term average level after the 2000 peak.

Finnish budget remained in substantial surplus under both measures, but in the Swedish case it is seen to have been in balance in 1999-2000, rather than in surplus. For Australia, the fiscal balance remained in deficit in the late 1990s when excluding capital gains tax revenues. For Italy and Japan, the effects of removing capital gains taxes on cyclically-adjusted balances are limited.

Capital gains tax receipts may be the most important single asset-price related revenue item, but a number of other avenues exist through which asset price fluctuations could affect the budget: stock options, tax revenues from defined-benefit private pension schemes, the impact of buoyant housing markets on transaction taxes, property taxes and inheritance taxes. These are generally less important quantitatively, but land and property transactions taxes can have a significant impact where prices are rising rapidly.

### *Stock options*

*Stock options have affected income tax revenues...*

The strength of the stock market until 2000 encouraged firms to rely more heavily on performance-linked compensation and stock options became an important component of executive pay in some countries. Estimates for the United States show that income from stock options rose from negligible amounts in the early 1990s to about 2 per cent of total wages and salaries in 2000.<sup>14</sup> This yielded individual income tax receipts of around ½ per cent of GDP, most of the income being concentrated among the highest earnings taxpayers and thus taxed at higher rates. Similarly, in the United Kingdom and Canada, the level of bonus payments in the form of stock options rose significantly at the end of the 1990s making up an increasing proportion of total earnings. Preliminary data suggest that income from stock options may have halved in 2001 and fallen even further in 2002.<sup>15</sup> In Finland, direct taxes from stock options increased from almost zero in 1998 to ½ per cent of GDP in 2000 before falling back to close to zero in 2002.<sup>16</sup>

*... but there are offsetting corporation tax effects*

In most OECD countries, gains from stock options are considered as labour income and are deductible from the corporate income tax (the main exceptions being Belgium, Canada, Germany and the Netherlands, where they are considered as capital income and are not a tax-deductible expense for companies).<sup>17</sup> Thus, for the United States, every dollar of option income realised by individuals generates an offsetting dollar reduction in corporate profits. Given these offsetting effects on profits, changes in equity prices

17. Companies generally receive a corporate income tax allowance corresponding to the assessed personal income of the employee derived from the option, to ensure the symmetric treatment relative to alternative forms of compensation (van den Noord and Heady, 2001).

and income tend to generate much smaller changes in total taxable income and total tax revenue than capital gains. Depending on the marginal rates of tax paid by individuals and companies, these effects could neutralise one another, suggesting that any adjustment that attempts to correct for stock options is in fact likely to make little or no difference.<sup>18</sup>

### *Corporate pension plans*

#### *Tax revenues from pension plans are affected by asset price cycles*

Tax revenues from defined-benefit pension plans, which were boosted by high investment returns in the late 1990s, are now affected by subsequent depressed returns. During the bullish capital market of the 1990s, many corporate sector defined benefit pension plans accumulated huge surpluses and several companies benefited from “funding holidays”, during which it was possible to reduce or entirely avoid contributions. This situation led to additional tax revenues as contributions are generally tax deductible. However, with the downward correction of equity prices in 2000, pension plans suffered important falls in funding levels and contributions from both employers and employees had to rise to reduce part of the funding gap, thus lowering tax revenues.<sup>19</sup> The extent to which the replenishment of pension funds will diminish tax revenues is, however, difficult to quantify, and incorporating such a correction into the cyclically-adjusted budget is impracticable.

### *Property, transaction and inheritance taxes*

#### *Taxes on immovable property follow cycles in house prices*

The administrative assessment of property values is often inaccurate, especially for owner-occupied housing, and property tax revenues follow housing market cycles only approximately, with a lag.<sup>20</sup> In the United States and Canada, these revenues are important and account for about 3 per cent of GDP. However, in European Union (EU) countries, tax on property as a share in GDP is small, with the notable exceptions of Luxembourg, the United Kingdom and France, and their fluctuations have only a minor impact on fiscal balances. In Japan, revenues from the taxation of property hardly moved during the boom period of the late

---

18 . However, these options may be exercised by employees of unprofitable firms, whose corporate tax liability is zero, yielding a net tax revenue gain (Congressional Budget Office, 2002).

19 . For example, in Canada, the value of assets in employers pension plans was down 11½ per cent at the end of 2002 and contributions more than doubled in 2002, decreasing tax revenues. In the Netherlands, second-pillar pension contributions, which are tax deductible, are expected to rise by some 4 percentage points to cover the underfunding of pension funds, worsening the fiscal balance by a cumulative 1¼ per cent of GDP by 2007 (Van Ewijk and Van de Ven, 2003). In Denmark, a year when stock market developments are “normal” generates taxation from the returns on pension fund investments of around 1 per cent of GDP (Finansministeriet, 2002), but the fall in equity prices and a change in tax rates on the return on assets resulted in fall in revenue from 1¼ per cent of GDP in 1999 to virtually zero in 2001-03.

20 . See Girouard and Price (2004).

1980's, remaining at around 1½ per cent of GDP until 1991, reflecting significant administrative undervaluation of property. This gap between the market prices and the assessed value shrank as the market prices went down during the second half of the 1990s.

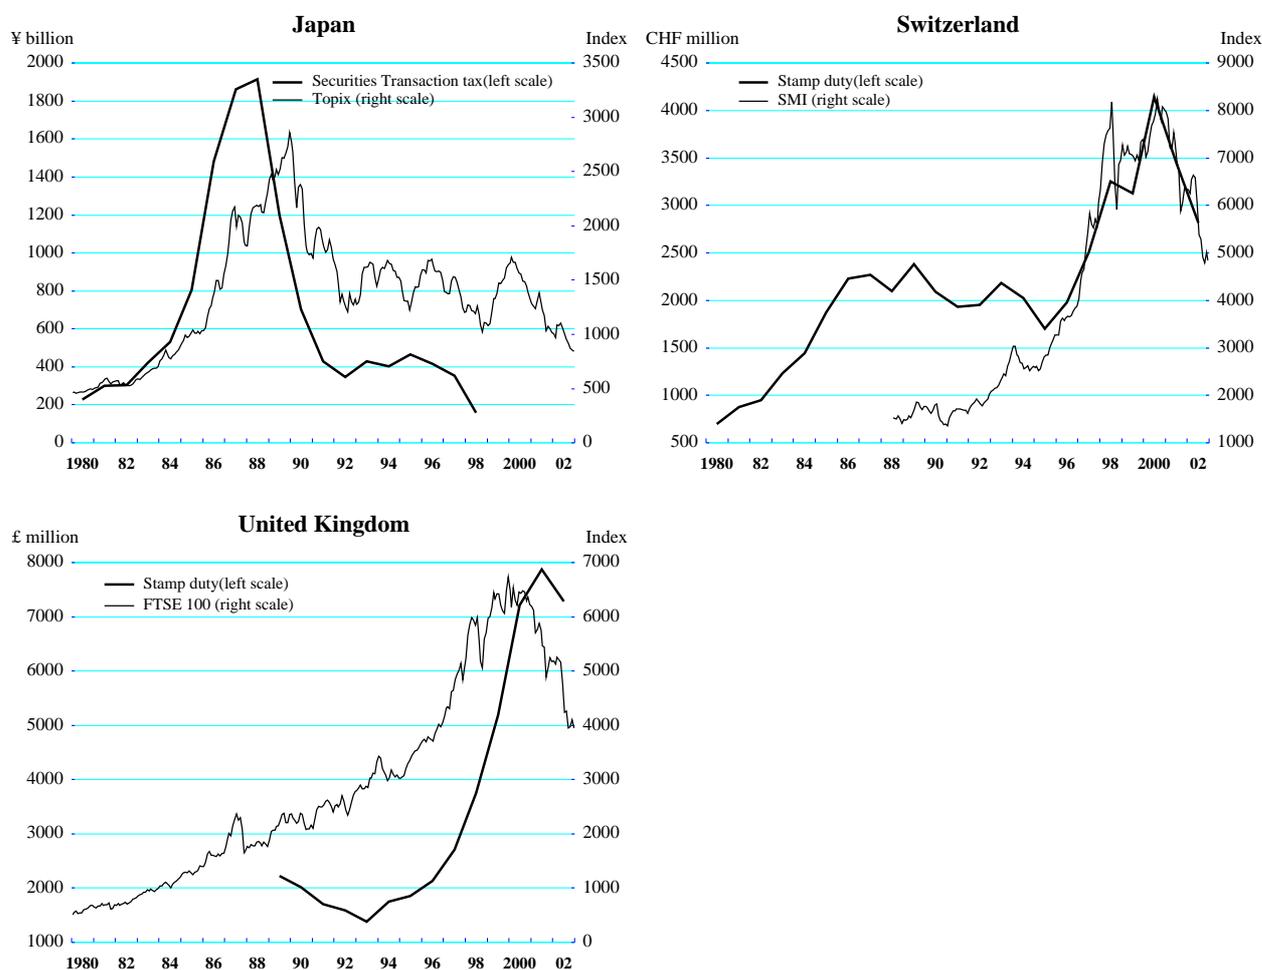

***Revenues from transaction taxes are sensitive to asset price swings***

Many governments draw revenues from transactions in assets, including taxes on the issue, transfer, purchase and sale of shares. In several countries, such tax revenues have followed movements in the stock market (Figure VI.5). As they represent a small share of GDP (about ¾ per cent of GDP for the OECD unweighted average), movements in transaction taxes generated small effects on fiscal balances. Countries experiencing the largest swings include Japan, where revenue from the transaction tax rose from close to zero in the early 1980s to ½ per cent of GDP at the peak of the stock market cycle before collapsing to almost zero following the bursting of the bubble (the transaction tax was abolished in fiscal year (FY) 1999). In the United Kingdom, revenues from the stamp duty increased from ¼ per cent of GDP in early 1990s to more than ¾ per cent in 2000 and 2001, owing to buoyant property and stock markets and, to a lesser extent, to past increases in tax rates. Revenues have flattened since, reflecting the offsetting impact of house and share price changes. In Switzerland, revenues from the stamp duty doubled between the mid-1990s and 2000 reflecting the large number of new stock emissions as well as buoyant trading volumes. These revenues have reverted to close to previous levels with the end of the stock market boom.

***Inheritance tax generates revenues from higher asset prices***

The taxation of the transfer of wealth has undergone some fluctuations in revenue due to asset price cycles. However, these revenues are small (the OECD unweighted average tax accounts for ¼ per cent of GDP) and tend to be accrued over a long period, as a rise in share prices may not bring additional revenues rapidly as it must await death. In the United States, revenues from the income of estates, inheritance and gift taxes increased from \$15 billion in 1990 to \$37 billion or close to ½ per cent of GDP in 2000 before falling to ¼ per cent of GDP in 2003. While changes in the tax laws in recent years make it difficult to determine the sensitivity of the estate tax to the stock market, in all likelihood, some additional revenues collected with this tax stemmed from rising asset prices. In the United Kingdom, the inheritance tax revenue has been very stable since 1990 at around 2 per cent of GDP as the impact of lower share prices has been offset almost entirely by the effect of higher house prices.

***In total, asset market swings made a major contribution to the revenue surprise***

Normally, the overall contribution of the above components to government receipts is quite small, but at times when there are large asset price swings the contribution to the annual change in revenues can be large. For the United States, for example, the Congressional Budget Office estimates that the share of asset-related receipts in total revenues rose from 6½ per cent to 14 per cent between 1994 and 2000, but they accounted for two-thirds of the increase in the ratio of federal receipts to GDP over the same period, contributing in major part to the overall revenue surprise.<sup>21</sup> And of this, capital gains taxation accounted for about one third.

21 . Congressional Budget Office (2002).

### Dealing with exceptional sources of budget change

*Other one-off revenue measures may embellish the budget figures...*

The above analysis is based on the proposition that an accurate assessment of the underlying fiscal stance requires that short-term fluctuations apart from those associated with the cyclical output gap should also be netted out of the budget picture. This principle can be generalised to other “one-off” factors, such as sales of operating licences to telecommunications providers, securitisation operations, exceptional dividends, payments to government by corporations in the context of transferred pension obligations, and public real estate asset sales.<sup>22</sup> All of these expedients have been used, at times, temporarily to augment government revenues.

*... and stock-flow adjustments may also reflect off-budget operations*

At the same time, deficit and debt positions are affected by initiatives to move expenditure and loan operations off-budget, the impact becoming evident as *ad hoc* periodic adjustments are made to outstanding government debt. These may occur in connection with the revaluation of financial assets and liabilities (including those associated with privatisations and exchange rate changes), or the writing-off of loans and the exercise of government guarantees. In practice, adjustments are not made to the deficit for such “one-off” debt adjustments. However, large and persistent discrepancies between deficit flows and changes in outstanding debt should give cause for concern, especially if recorded deficits systematically understate debt rises.

#### *“One-off” revenue operations*

*UMTS licence proceeds significantly altered budget figures...*

The treatment of “one-off” revenues associated with sales of Universal Mobile Telecommunications Systems (UMTS) licences has become an important issue for fiscal reporting and analysis since the amounts involved were substantial for some countries.<sup>23</sup> The OECD follows the internationally agreed approach where the allocation of the licence is treated as a sale of an asset when the licence is granted for a long term and when the transaction amount is known with certainty from the beginning. Under these conditions, the sale proceeds are recorded as negative investment on the expenditure side of the accounts and are reflected in a “one-off” improvement in the general government financial balance, equal to the total amount of the disposal and recorded at the time the licence is allocated.

---

22 . See for example Milesi-Ferretti (2000) for a discussion of creative accounting and fiscal rules.

23 . In 2000, UMTS revenues accounted for 2.5 per cent of GDP in Germany, 1.2 per cent of GDP in Italy, 0.7 per cent of GDP in the Netherlands and 2.4 per cent of GDP in the United Kingdom.

***... as have securitisation operations***

In recent years, some EU countries governments have increasingly securitised financial or non-financial assets and revenue flows,<sup>24</sup> and the size of some of these operations has been large. In 2002, the Statistical Office of European Communities (Eurostat) released guidelines identifying the conditions under which the receipts from securitisations could be used to reduce the general government net borrowing.<sup>25</sup> The implementation of the new guidelines has been reflected in an upward adjustment of the fiscal deficit for Italy by about  $\frac{3}{4}$  per cent of GDP in 2001 and the debt position for Austria and Greece (by  $3\frac{1}{2}$  per cent of GDP in 2000-01 for Greece).<sup>26</sup>

***Other expedients used to reduce deficits include exceptional dividends...***

Exceptional dividends, arising from sales by state-owned entities of assets or realised capital gains at the request of government, have been used to reduce general government net borrowing in several countries. However, the European System of Accounts (ESA95) rules imply that “one-off” payments from such transactions, should not be recorded as dividends. As a consequence, the Portuguese general government deficit for 2002 was revised up by Eurostat, to exclude the proceeds received by the government at the occasion of the liquidation of the industrial development fund of the European Free-Trade Agreement (EFTA). Similarly, the ESA95 rules imply that exceptional payments made to general governments by central banks, following transactions in reserve assets that are not part of the normal activity of monetary authorities, should have no impact on government net borrowing. In some EU countries, seignorage revenues from the euro cash changeover had been considerable. In Greece for example, the reclassification of the proceeds from coinage required by Eurostat has lowered government revenues by an amount equal to almost  $\frac{1}{2}$  per cent of GDP.<sup>27</sup>

***... transfers of pension obligations...***

By contrast, “one-off” compensation payments, registered to the government when pension obligations are transferred from corporations to the state, can be used to reduce financial deficits in some EU countries. These payments, which are recorded as government revenue at the time they occur, will be offset in the future by the payment of pension benefits for which the government becomes responsible.<sup>28</sup> In France, the 1997 deficit was reduced by a payment of  $\frac{1}{2}$  per cent of GDP for the partial takeover of pension liabilities by the government prior to France Telecom’s privatisation. In Portugal, following the transfer of postal services pension fund, the deficit was reduced by  $\frac{3}{4}$  per cent of GDP in 2003.

---

24 . Securitisation is defined as an arrangement where the owner of an asset transfers the ownership to another unit, often called a Special Purpose Vehicle, which borrows to pay the seller, generally in the form of securities issued on its own account.

25 . In particular, the price paid for the assets by the Special Vehicle to the government needs to be at least 80 per cent of the market price.

26 . See Eurostat (2002a and 2002b).

27 . See European Commission (2003).

28 . See Eurostat (2004).

***... and sales of non-financial assets***

Sales of non-financial assets such as buildings or land can be treated as capital receipts in the national accounts and as such may have a positive impact on the net lending of the general government. In Italy, sales of public real estate assets amounted to about ½ per cent of GDP in 2002. In Belgium, the improvement in the cyclically-adjusted balance was due, in part, to a sharp reduction in net government capital outlays between 2000 and 2002. Following the boom in local public investment, which had eroded the general government balance in 2000, public asset sales boosted it by ¼ per cent of GDP in 2002.<sup>29</sup>

***Financial transactions and debt adjustments******Deficits of state-owned entities may be covered by capital injections...***

Just as fiscal deficits may be understated by treating one-off “below-the-line” receipts as current revenues, they may also be reduced by treating capital injections into state-owned enterprises as “below-the-line” items when they really represent subsidies. In France, the fiscal deficit has been revised upwards by Eurostat to include the capital injection from the French State to the Railway System. The revision amounted cumulatively to close to ½ per cent of GDP between 1999 and 2002.<sup>30</sup> Chronic deficits of coal industry (*Charbonnage de France*) have also been covered through capital injections that were spuriously treated as financial transactions.

***... and there may be large ex post revisions to deficits and debt***

Imprecise recording of budgetary operations can lead to large *ex post* upward revisions in deficit and debt levels.<sup>31</sup> In Portugal, in recent years, there has regularly been a difference between the general government borrowing requirement and changes in the public debt, which have been larger than would have been implied by budget deficit flows. This difference has reflected off-budget operations, privatisations, or the absorption of unexpected debts and is estimated to have reached more than 2½ percentage points of GDP in 2002.<sup>32</sup> In Italy, Greece and Belgium, the behaviour of the stock of debt has also been negatively affected by stock-flow adjustments.<sup>33</sup>

**Box VI.1. Country specific approaches to correct for asset-price effects**

In the United States, the Congressional Budget Office calculates a structural budget balance (the so-called standardised-budget balance) which removes temporary factors not directly connected with changes in policy as well as the effects of the business cycle. Those factors include unusually large discrepancies between tax payments and liabilities, swings in collections of capitals gains taxes, changes in the inflation component of the government's net interest payments, temporary legislative changes in the timing of revenues, and outlays and receipts from the government sale of assets and from auctions of licences to use the electromagnetic spectrum. Removing those tax receipts avoids the misleading effects that can arise, for example, when a cut in the tax rate on capital gains temporarily encourages the realisation of taxable gains by enough to increase revenues. That rise in revenues causes the structural budget measure to indicate -- incorrectly -- that a tax cut implies budgetary restraint on the growth of real income in the short term.

In France, the concept of "structural effort" was proposed in the 2004 draft Budget to help capture the true discretionary component of fiscal policy.<sup>1</sup> It permits a decomposition of the structural balance into discretionary and non-discretionary components. The "structural effort" -- or discretionary component -- identifies a "structural spending effort", specified by the gap between public spending growth and potential growth, and a "structural receipt effort" defined as new tax measures. The decomposition illustrates that tax elasticities were temporarily above 1 between 1999 and 2001, helping to improve the structural balance without any new discretionary measures. Conversely, tax elasticities were below 1 in 2002 and 2003, contributing to a deterioration in the structural balance.

In the United Kingdom, the assumptions underlying the Treasury's economic projections include a growth path for share prices. In the 2002 Budget for example, the share prices assumption was that the FTSE All-Share index would rise in line with nominal GDP. However, share prices turned out to be 23 per cent lower than the Budget forecast for 2002-03 and 25 per cent lower for 2003-04. Outturns dependent on these assumptions can be separately identified and the decomposition of forecast errors permits a distinction to be made between fiscal developments related to the economic cycle and those which are not.

In Canada, a methodology for estimating an indicator of budgetary position has been developed addressing in particular, the problem of simultaneity between economic and fiscal variables.<sup>2</sup> Results indicated a larger cyclical component in absolute terms under the new methodology which corrects bias in estimates by using Generalised Method of Moments estimation.

In Switzerland, a method to filter out irregular revenue components has been proposed.<sup>3</sup> It is based on revenue ratios for which a normal or structural level is determined using "expert insight" rather than a purely mechanical approach. The structural part of expenditure is also determined taking into account the earmarked part of a number of federal taxes.

In Hungary, the central bank uses an analytical indicator for budget accounting which represents a transition between the statistical approaches of the IMF's Government Finance Statistics and the European Commissions' European Standard Accounts.<sup>4</sup> The main adjustments include: exclusion of "one-off" revenues and off-budget activities financed by *ex post* capital injections.

In Portugal, the methodology recently adopted by the central bank to estimate cyclically-adjusted balances captures the impact of different growth patterns on the revenues and expenditures. The tax elasticities are related to proxies of the individual tax bases and not to overall output. Thus, the cyclical adjustment is not independent of the composition of GDP. The new methodology excludes the final withholding tax levied on most capital income categories received by households from the personal income tax revenues to be cyclically-adjusted. It also introduces an asymmetric lag on the cyclical component of the corporate income tax to take into account the effects on fiscal revenue of prepayments made by companies.<sup>5</sup>

### **Making adjustments for the impact of non-structural factors**

*Irregular revenue components are increasingly netted out...*

Adjustment for the above influences has to proceed on an *ad hoc* and case-by-case basis and no systematic classification yet exists. As far as the OECD budget indicator is concerned, adjustments are made in important instances, such as UMTS licence receipts and the securitisation of financial or non-financial assets.<sup>34</sup> Most countries do not attempt to smooth the budget balance series for such influences. However, a number have begun to make adjustment for “one-off” revenue shifts as well as some asset-price effects (Box VI.1).

*... but no single structural fiscal indicator fits all purposes*

Thus far, such approaches are quite disparate, and the creation of a set of internationally consistent indicators which adjusts for all the factors listed in this chapter is prohibited by uneven fiscal data coverage between countries. However, the experience of the past cycle, when inaccurate estimates of the structural budget position gave misleading signals to policy-makers, emphasises the need for underlying budget measures to be more accurately assessed for temporary influences in the next upturn.

---

34 . Other factors accounted for by the OECD but not discussed here include deferred tax payments on matured postal saving accounts in Japan, revenue from oil and gas activity on the continental shelf and the petroleum fund in Norway and tax amnesties introduced in several countries.

*Appendix*  
**Measuring discretionary and autonomous fluctuations in tax revenue**

This appendix presents the methodology used in Table VI.2 to measure the extent to which the abrupt revenue increases and declines over the 1995-2002 period have reacted to non-discretionary factors such as the boom and bust in the equity market.<sup>35</sup> It does so by identifying the change in revenues that cannot be explained by cyclical variations in output and discretionary fiscal policy measures alone. Two categories of tax are distinguished: direct taxes on businesses and direct taxes on households.

The calculations of residual revenue shifts are based on actual GDP outcomes and *ex post* estimates of the output gap, to remove the source of error due to “misforecasts” of output growth:

$$RR_{i,j} = R_{i,j} - PR_{i,j}$$

where:  $PR_{i,j} = R_{i-1,j} * [1 + (bY_{i,j} - bY_{i-1,j}) * E_j / bY_{i-1,j}] + D_{i,j}$

with  $RR$  = residual revenue;  $R$  = actual revenue;  $PR$  = predicted revenue;  $bY$  = tax base;  $Y$  = national income;  $b$  = ratio of taxable to total national income/output;  $D$  = effect of discretionary measures;  $i$  = period;  $j$  = tax category; and  $E$  = elasticity of tax revenue with respect to tax base.

The tax elasticities are based on OECD estimates, with the individual elasticities assumed to be constant over the observation period (van den Noord, 2000). National estimates of discretionary policy change relate to federal government for Canada and to central government for France<sup>36</sup> and the United States and are based on their projected impact provided at the time of enactment. These estimates assume that discretionary measures will remain constant over the budget period at the level prevailing at the beginning of the period and thus represent only an approximation of the magnitude of the true discretionary policy changes. Tax bases for household direct tax comprise dependent wage income, self-employment

---

35 . See also Eschenbach and Schuknecht (2002b) for a similar methodology.

36 . The French data for discretionary measures in 1998 have been adjusted by € 30 billion to take into account the tax switch reflecting the changes in the financing of the social security system.

income, property income and current transfers. The tax base for corporate income tax includes total economy output minus compensation of employees, self employment and indirect taxes plus subsidies.<sup>37</sup>

The above equation can be broken down one step further to expose more clearly measurement problems and to clearly identify changes due to built-in stabilisers *i.e.* changes in the output gap and changes in trend growth *i.e.* changes in potential output. If  $Y$  is decomposed into potential output and the output gap, the tax base can be re-written as:

$$bY = b(Y^* - Y) + bY^*$$

where  $(Y^* - Y)$  is the output gap ( $GAP$ ) and  $Y^*$  is potential output. The equation then becomes:

$$PR_{i,j} = R_{i-1,j} * [1 + (b(GAP_{i,j} - GAP_{i-1,j}) + b(Y^*_{i,j} - Y^*_{i-1,j})) \\ * e_j / bGAP_{i-1,j} + bY^*_{i-1,j}] + D_{i,j}$$

Cyclically-adjusted revenues are calculated by setting the term  $[GAP_{i,j} - GAP_{i-1,j}]$  to zero. There are several possible sources of error linked to the computation of output gaps. Well-known measurement issues relate to the pro-cyclical bias of estimates of potential output, and hence of the output gap. Potential output may be overestimated and the cyclical component of revenue growth  $(b(GAP_{i,j} - GAP_{i-1,j}))$  underestimated. At the same time, the nature of any change in the tax base with respect to income may be misinterpreted as structural, when it actually derives from an underestimate of the cyclical tax elasticity: *i.e.* the “excess” revenues due to unforeseen tax buoyancy would appear as part of the cyclically-adjusted component of the deficit.

The calculations are rebased each year, so that the total error over any period is the sum of the annual residuals.

---

37. Definition and measurement of tax bases corresponding to the different types of revenues are often inaccurate and the order of magnitude provided in this paper should therefore be interpreted with cautious. Methodological problems associated with the calculation of effective tax rates are spelled out extensively in Carey and Rabesona (2002).
