STI Working Paper Series

The Working Paper series of the OECD Directorate for Science, Technology and Industry is designed to make available to a wider readership selected studies prepared by staff in the Directorate or by outside consultants working on OECD projects. The papers included in the series cover a broad range of issues, of both a technical and policy-analytical nature, in the areas of work of the DSTI. The Working Papers are generally available only in their original language – English or French – with a summary in the other.

Comments on the papers are invited, and should be sent to the Directorate for Science, Technology and Industry, OECD, 2 rue André-Pascal, 75775 Paris Cedex 16, France.

The opinions expressed in these papers are the sole responsibility of the author(s) and do not necessarily reflect those of the OECD or of the governments of its member countries.

THE OECD INPUT-OUTPUT DATABASE: 2006 EDITION*

Norihiko Yamano and Nadim Ahmad

ABSTRACT

The development of the OECD's input-output database started over a decade ago and is currently undergoing its second update. Over the years, the database has been used in a number of analytical applications both within and outside the OECD. Two major applications within the OECD concerned the analysis of the diffusion of embodied technology and, more recently, the measurement of carbon dioxide emissions embodied in the international trade of goods. The latest update is being conducted as part of an OECD project looking at global value chains. This paper describes how the database has developed over the last decade, both from a collection and a compilation perspective, and some of the thinking behind the various assumptions used during compilation and the various pre-requisite data needed to compile the tables. The paper also outlines the rationale for producing these harmonised tables on an industry-by-industry basis rather than product-by-product; partly reflecting the importance of linking the tables to many other OECD databases. The purpose of the paper is therefore twofold. The first is to describe the database and its uses. The second is to describe the OECD's experience in the compilation of these tables in the hope that this may benefit input-output compilers in national statistical offices and provide them with a better understanding of the information needed by the OECD to compile these tables in order to meet the demands of users.

* The authors would like to thank the multitude of test users for their comments as well as national statistics institutes and Norihisa Sakurai for their valuable assistance in providing data.

LA BASE DE DONNÉES ENTRÉES-SORTIES DE L'OCDE : ÉDITION 2006*

Norihiko Yamano et Nadim Ahmad

RÉSUMÉ

Le développement de la base de données entrées-sorties de l'OCDE a débuté il y a une dizaine d'années et est actuellement en phase de seconde mise à jour. Au fil des ans, cette base de données a été utilisée dans un certain nombre d'applications analytiques au sein et à l'extérieur de l'OCDE. Au sein de l'OCDE, les deux principales études ont porté sur l'analyse de la diffusion des technologies intrinsèques et, plus récemment, de la mesure des émissions de dioxyde de carbone afférentes au commerce international de biens. La toute dernière mise à jour menée par l'OCDE fait partie intégrante d'un projet traitant des chaînes de valeurs mondiales. Le présent document décrit comment la base de données a été développée au cours des dix dernières années, aussi bien du point de vue de la collecte que de la compilation des données ; il fait également état des quelques réflexions tirées des diverses assomptions utilisées au cours de la compilation et des diverses données pré-requises nécessaires à l'élaboration des tableaux. Ce papier souligne aussi l'intérêt de construire des tableaux harmonisés sur la base d'une ventilation de type industrie par industrie plutôt que produit par produit – reflétant en partie l'importance de lier ces tableaux à plusieurs autres bases de données de l'OCDE. Le but de ce document est donc double. Premièrement, de décrire la base de données et ses usages. Deuxièmement, de décrire l'expérience de l'OCDE dans la compilation de ces tableaux dans l'espoir qu'ils puissent servir aux compilateurs de données d'entrées-sorties des bureaux nationaux de la statistique et leur fournir une meilleure compréhension de l'information requise par l'OCDE pour compiler ces tableaux afin de satisfaire les demandes des analystes.

* Les auteurs remercient tous ceux et celles qui se sont portés volontaires pour tester la base de données pour leurs commentaires, ainsi que les offices nationaux de statistiques et Norihisa Sakurai pour les données qu'ils ont bien voulu leur fournir.

ANNEX II: RECENT COUNTRY TABLES 25

1. Introduction and history

The first edition of the OECD Input-Output (I-O) Database dates back to 1995 and covered 10 OECD countries spanning the period 1968 to 1990. The first update to this database began in 2000 culminating in the 2002 edition[1] of the database, which increased the country coverage to 18 OECD and 2 large non-OECD countries, spanning the period 1992 to 1997. Work on the second update of the database, the 2006 edition, began in 2005 with coverage extended to 28 OECD and 9 non-OECD countries. These latest tables are based around the year 2000 for most countries, though for some, more recent years are provided (for example, 2003 for Mexico).

This paper is organised as follows: Section 2 describes the purpose of the OECD I-O Database; Section 3 describes the data sources; Section 4, the coverage of the database itself; Section 5, the preferred price basis used by the OECD; Section 6, the format of the tables; Section 7 describes, in detail, the transformation processes used by the OECD to arrive at harmonised tables; and finally Section 8 provides an explanation for the industry-by-industry presentation preferred by the OECD.

2. Purpose

Input-output tables describe the sales and purchases relationships between producers and consumers within an economy. They can be produced by illustrating flows between the sales and purchases, both final and intermediate, of *industry outputs* or by illustrating the sales and purchases, both final and intermediate, of *product outputs*. The OECD Input-Output Database is presented on the former basis, reflecting in part the collection mechanisms for many other databases such as R&D expenditure data, employment statistics, pollution data and energy consumption, which are often collected by establishment or enterprise and grouped according to classifications of industrial activity (Section 4 shows the industries used in the I-O Database). They lend themselves to a number of uses that, in the main, can be categorised under two headings: analytical or statistical. Examples of the former include analyses that identify the importance of any industrial sector or product to economic output or growth, not just as a share of gross value-added, say, but as a contributor of activity or growth in other sectors *e.g.* via embodied analyses methods. Increasingly, they are also being used in environmental analysis – for example, to measure direct and indirect pollutants produced by industrial activity within an economy and importantly, to contribute to "footprint" or "embodied" type analyses. Indeed these are the most recent types of application of the database within the OECD[2] and many other institutions.[3]

As a statistical analysis tool, input-output and the closely related supply-use tables are increasingly becoming the vehicles used to balance the income, expenditure and production estimates of GDP and as the basis for other statistical measures, such as productivity estimates, in particular multi-factor productivity estimates (for example, the EU KLEMS project[4]). In terms of international comparability they are also used as a diagnostic statistical tool, for example some National Statistics' Institutes use the OECD harmonised tables in a diagnostic way to assist the construction of their own input-output tables. Indeed, the 2002 edition of the tables provided input into the work of the OECD Task Force on Software Measurement, by comparing the widely different relationships between intermediate consumption and investment on software across countries (Ahmad, 2003).

1. Ahmad (2002). Go to www.oecd.org/std/io-tables/data to obtain the 2002 edition of OECD input-output tables for free.

2. Ahmad and Wyckoff (2003).

3. For example, http://www.mosus.net/project-index.html.

4. See http://www.euklems.net/.

The maintenance and updating of the OECD's Input-Output Database is necessarily financed via voluntary contributions. In practice this means that the database update always has a designated user-application since it is, by design, demand driven. The first edition, for example, was motivated by the desire to measure the diffusion of technology embodied in products (Papaconstantinou *et al*., 1996; Sakurai *et al*., 1996) while the second edition was mainly developed to measure the importance of CO_2 emissions embodied in goods (Ahmad and Wyckoff, 2003). The current edition has been mainly motivated by a recent OECD project on global value chains[5] and to update the 2003 work on embodied CO_2 emissions.

However the usefulness of the database extends far beyond these specific applications. By making them freely available on request the OECD Input-Output tables have served as important inputs into a wide range of economic analyses, including work on productivity, technology diffusion, global warming, structural change and several other issues.[6]

Between December 2004 and May 2006, the OECD received over 550 requests from 50 different countries for the 2002 edition of the database (exact records were not kept before this period but the number of users also extended into the hundreds). Of these 550 users, just over half are affiliated to academic institutions and the remainder to private and government institutions. 55% of the users are from OECD European countries, 21% from NAFTA countries, 9% from other OECD countries and 14% from non OECD member countries.

In an effort to ensure that the database retains its relevance and meets users' needs as much as possible, users were recently asked if they could provide information on those areas where they would welcome improvements. Not surprisingly, wider country coverage, a more detailed industry sector breakdown and more recent tables scored highly. As will be shown in the following sections it is precisely in these three areas that the 2006 edition has seen considerable improvements. However other improvements have also been incorporated such as improved international harmonisation of the price bases.

3. Data sources

The process of compiling the database begins with requests to national statistical institutes (NSIs) to provide data in accordance with a harmonised industry structure based on the International Standard Industrial Classification of all Economic Activities (ISIC). ISIC Revision 3 provides the basis for the 2006 edition as was the case for the 2002 edition (the 1995 edition was compiled on the basis of ISIC Revision 2). However in order to minimise compliance costs, and to maximise co-operation, the requests stipulate that this pro-forma is not a pre-requisite, and that any relevant data (input-output and/or supply-use tables) at the most detailed and practicable level are welcomed in any (detailed) format. As shown in the table below most countries have chosen to deliver data using their own industrial classification systems and standard presentation in response to the latest request. The request for supply-use tables, in addition to input-output tables, is partly in recognition of the increasing importance of supply-use tables to NSIs within their national accounts frameworks, and, as a consequence, their availability. However it mainly reflects the fact that a number of countries do not produce input-output tables but do produce supply-use tables which can be easily converted into input-output tables using some standard assumptions – see Section 7. Table 1 summarises the information received for each country's latest table in the OECD database.

5. See Pilat (2006).

6. See Wixted, Yamano and Webb (2006), for a discussion on various analytical uses of input-output tables.

c: Commodity-by-commodity tables; PU: Purchasers' Prices; PR: Producers' Prices.
(i) For these countries a breakdown of value-added into its separate components, such as labour, operating surplus etc, was not provided – estimates were made using the proportions provided in the OECD's Structural Analysis (STAN) Database. Domestic use and I-O tables are not shown in the table above but it follows that if "total" and "import" tables exist then so too does the domestic table.
(ii) Available in November 2006.
(iii) Tables for Singapore are available within the OECD only.

This, of course, is only the first part of the process. Each of the submissions, and those received in earlier years, need to be converted onto a harmonised basis – harmonised in the sense that they are: industry-by-industry; on the same price basis (basic prices); aligned to the industry classifications used in the OECD system; and aligned in their treatment of concepts. This process of conversion is explained in more detail in the following sections, including other adjustments needed to overcome differences in some concepts, most notably the treatment of financial intermediation services indirectly measured (FISIM) and differences in the treatment of other items such as non-residents' expenditure and residents' expenditure abroad.

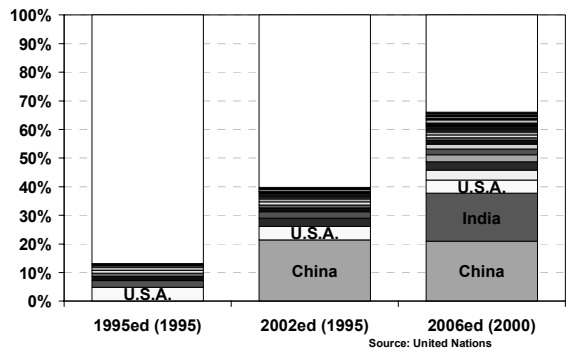

4. The database

4.1 Coverage – country and time

The 2002 edition of the OECD Input-Output Database saw the number of countries covered increase from 10 (OECD) to 20 (18 OECD and 2 non-OECD) compared to the 1995 edition. The 2006 edition has continued this expansion and includes 37 countries (28 OECD and 9 non-OECD) further strengthening the ability of the database to allow the analysis of global issues. The effects of globalisation and increased foreign outsourcing of manufacturing goods and services for example cannot be fully analysed if some of the larger OECD countries such as Mexico and emerging non-member economies such as India, Indonesia and Russia are not included. These countries have been included for the first time – as have Austria, Belgium, Ireland, Portugal, New Zealand, Slovak Republic, Sweden, Switzerland, Turkey, Argentina, Chinese Taipei, Israel, Singapore (although tables for India, New Zealand, Russia and Sweden were available for OECD internal use in the 2002 edition).

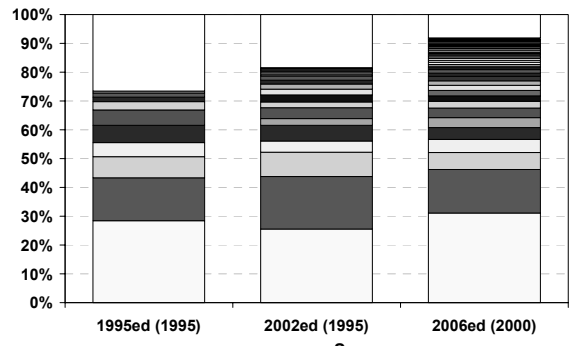

Table 2 below summarises the coverage of the database, showing the years and countries for which data are currently available. The table also shows, for convenience, GDP estimates for each country in 2000 expressed in USD together with each country's global GDP ranking and population in 2000. An interesting way of illustrating how the coverage of the database has increased over time is to consider the share of global population and global GDP covered by the countries within the database over the various editions of the database. This shows that coverage in terms of population rose from just over 10% in the 1995 edition to 40% in the 2002 edition and 66% in the 2006 edition. The coverage in terms of nominal USD-based GDP has also increased from just over 70% (1995 edition) to 80% (2002 edition), and over 90% in the 2006 edition; which in turn reflects 95% of total OECD GDP (see figures 1 and 2).

Figure 1. **OECD I-O Database share of global population by edition**

1995 edition: Australia, Canada, Denmark, France, Germany, Italy, Japan, Netherlands, United Kingdom and United States. **2002 edition, added** Czech Republic, Finland, Greece, Hungary, Korea, Norway, Poland, Spain, Brazil and China.

Figure 2. **OECD I-O Database share of global GDP by edition**

2006 edition, added: Austria, Belgium, Ireland, Mexico, New Zealand, Portugal, Slovak Republic, Sweden, Switzerland, Turkey, Argentina, Chinese Taipei, India, Indonesia, Israel, Russia and Singapore.

"-": not available. Items in bold highlight tables compiled with the expanded industrial sector coverage (48) used in the 2006 edition, which includes updates to some country's tables from the 2002 edition. All other entries in the 1995 column were compiled at the 41 sector level used in the 2002 Edition. ISIC Rev 2 tables were compiled at the 35 industry level. "c" indicates a commodity-by-commodity table. *(i)* Tables for Singapore cannot be made available via the OECD and are for OECD internal use only.

4.2 Coverage – industries

The industry classification of the database (2006 and 2002 editions) is based on the ISIC Rev. 3 system, meaning that it is compatible with the OECD's structural analysis (STAN) industry database[7] and Bilateral Trade Database (BTD), IEA's energy consumption data, and other OECD industry-level databases.[8] The 1995 edition was based on the earlier ISIC Revision 2 system, which is broadly comparable to ISIC Revision 3 at the industry level presented.

The number of industries in the 2006 edition has been expanded to 48, 6 more than in the 2002 edition and 13 more than the 1995 edition. A full listing of the 48 industries is provided in Table 3. Comparing the 2006 and 2002 editions, more detailed industry information is available in the following areas:

a) *Mining and quarrying (ISIC 10-14)* has been split into two sectors: Energy Mining (ISIC 10+11+12) and Non-energy Mining (ISIC 13+14).

b) *Electricity, gas and water supply (ISIC 40+41)* has been split into 4 sectors: Production, collection and distribution of electricity (ISIC 401); Manufacture of gas, distribution of gaseous fuels through mains (ISIC 402); Steam and hot water supply (ISIC 403); and Collection, purification and distribution of water (ISIC 41).

c) *Transport and storage (ISIC 60-63)* has been split into 4 sectors: Land transport; Transport via pipelines (ISIC 60); Water transport (ISIC 61); Air transport (ISIC 62); and Supporting and auxiliary transport activities, activities of travel agencies (ISIC 63).

Unfortunately, information on all 48 industrial sectors could not be obtained for every country, reflecting a number of factors that vary by country – these include disclosure restrictions and a lack of detailed statistical sources, but in the main this reflects the loss of industry detail that can occur when moving from a national classification system to ISIC Rev.3. Table 4 illustrates this by describing, for each country, those sectors where imperfect concordances exist between national input output industries, and the requisite ISIC Rev. 3 industries. The table shows for each country, instances where certain activities are included in other I-O industries or missing from others. The concordance relationships used in earlier years typically differ and are described in the relevant notes at www.oecd.org/dataoecd/20/37/34085996.pdf.

7. www.oecd.org/sti/stan.

8. Go to http:/unstats.un.org/unsd/cr/registry/regcst.asp?Cl=2 for a full description of ISIC Rev.3.

Table 3. **OECD I-O Database – Industry classification and concordance with ISIC Rev. 3, 2006 edition**

ISIC Rev. 3 code	IO industry	Description
1+2+5	1	Agriculture, hunting, forestry and fishing
10+11+12	2	Mining and quarrying (energy)
13+14	3	Mining and quarrying (non-energy)
15+16	4	Food products, beverages and tobacco
17+18+19	5	Textiles, textile products, leather and footwear
20	6	Wood and products of wood and cork
21+22	7	Pulp, paper, paper products, printing and publishing
23	8	Coke, refined petroleum products and nuclear fuel
24ex2423	9	Chemicals excluding pharmaceuticals
2423	10	Pharmaceuticals
25	11	Rubber and plastics products
26	12	Other non-metallic mineral products
271+2731	13	Iron & steel
272+2732	14	Non-ferrous metals
28	15	Fabricated metal products, except machinery and equipment
29	16	Machinery and equipment, nec
30	17	Office, accounting and computing machinery
31	18	Electrical machinery and apparatus, nec
32	19	Radio, television and communication equipment
33	20	Medical, precision and optical instruments
34	21	Motor vehicles, trailers and semi-trailers
351	22	Building & repairing of ships and boats
353	23	Aircraft and spacecraft
352+359	24	Railroad equipment and transport equipment n.e.c.
36+37	25	Manufacturing nec; recycling (include Furniture)
401	26	Production, collection and distribution of electricity
402	27	Manufacture of gas; distribution of gaseous fuels through mains
403	28	Steam and hot water supply
41	29	Collection, purification and distribution of water
45	30	Construction
50+51+52	31	Wholesale and retail trade; repairs
55	32	Hotels and restaurants
60	33	Land transport; transport via pipelines
61	34	Water transport
62	35	Air transport
63	36	Supporting & auxiliary transport activities; activities of travel agencies
64	37	Post and telecommunications
65+66+67	38	Finance and insurance
70	39	Real estate activities
71	40	Renting of machinery and equipment
72	41	Computer and related activities
73	42	Research and development
74	43	Other Business Activities
75	44	Public administration and defence; compulsory social security
80	45	Education
85	46	Health and social work
90-93	47	Other community, social and personal services

5. Price basis

In line with the 1993 System of National Accounts (SNA93), the OECD Input-Output Database (2002 and 2006 editions) shows transactions, wherever possible, at basic prices.[9] Most European countries follow the basic price valuation system in producing symmetric input-output tables. However, supply-use tables, which are the core building blocks used by the OECD to produce industry-by-industry input-output tables, typically show intermediate and final demand transactions in purchasers' prices. The process of converting these into basic prices is described in Section 7.

6. Format of the tables

6.1 Value added components

The OECD Input-Output Database provides data on the following components of value-added (and other items that contribute to the differences between gross output at basis prices and intermediate consumption of domestically produced goods at basic prices), as shown in the table below, and where the definitions of each component are in line with those given in SNA93.

Table 5. **Measures provided in the OECD Input-Output Database (rows)**

	Description
(a)	Intermediate supply from industry 1
	…
	Intermediate supply from industry 48
(b)	Other adjustments (purchases on the domestic territory by non-residents)
(c)	Non-comparable import (cif/fob adj direct purchases abroad by residents)
(d)	Imports*
(e)	Intermediate consumption/final use at basic price
(f)	Net taxes on products
(g)	Intermediate consumption/final use at purchasers' price [e+f]
(h)	Value added at basic price [i+j+k]
(i)	Compensation of employees
(j)	Net taxes on production
(k)	Gross operating surplus
(l)	Industry output [g+h]

* Domestic table only.

9 . For convenience, descriptions of the relationships between purchasers/producers' prices and basic prices are shown below for key aggregates:

- Intermediate demand at purchasers' prices = Intermediate demand at basic prices + Taxes on products (sales tax, consumption tax, non-deductible VAT) – Subsidies on products.
- Gross output at basic prices = Gross output at producers' prices – Taxes on products (not including VAT and import taxes) + Subsidies on products.
- Value added at basic prices = Gross output at basic prices – Intermediate consumption at purchasers' prices.
- Value added at basic prices = Value added at producers' prices – Taxes on products (not including VAT and import taxes) + Subsidies on products.

6.2 Final demand components

Table 6 below describes the final demand components shown in the database. However, not all countries are able to provide such a breakdown. Indeed only 10 countries report "valuables" separately, which is instead (typically) included within changes in inventories, and 20 countries, NPISH, which is included within HHFC. As was the case for the components of value-added, the definitions of each item of final demand are consistent with SNA93.

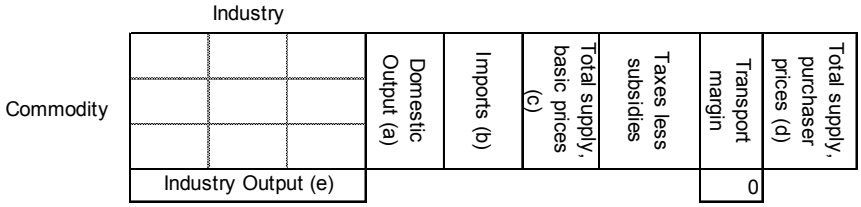

Table 6. **Measures provided in the OECD Input-Output Database (columns)**

	Description
(a)	Intermediate demand of industry 1 … Intermediate demand of industry 48
(b)	Total intermediate consumption
(c)	Final consumption expenditure by households [HHFC]
(d)	Final consumption expenditure by non-profit org. serving households [NPISH]
(e)	Final consumption expenditure by government
(f)	Gross fixed capital formation [GFCF]
(g)	Changes in inventories
(h)	Valuables
(i)	Exports
(j)	Imports (less)
(k)	Discrepancy

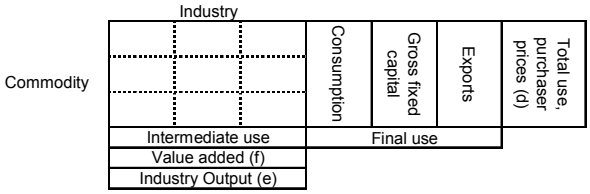

In summary, the 2006 edition of the OECD Input-Output tables follows the format of earlier editions, with the exception that the industry set has expanded since the 2002 edition. Annex II presents total economy (domestic + import) symmetric input-output tables at an aggregate industry level for each country.

Box 1. **Structure of supply, use and symmetric tables**

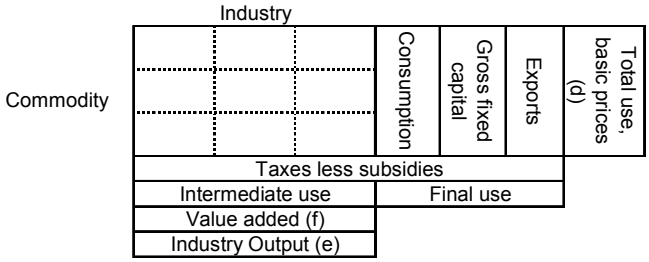

A. Supply table with basic prices conversion

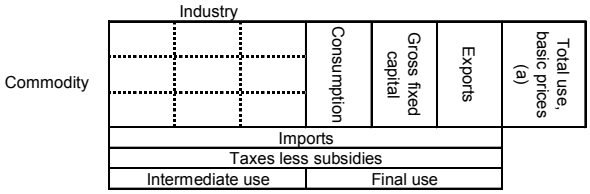

B. Use at purchasers prices (total)

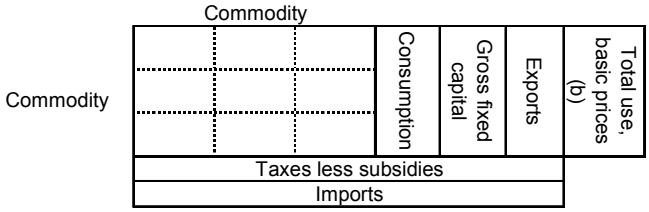

C. Use at basic prices (total)

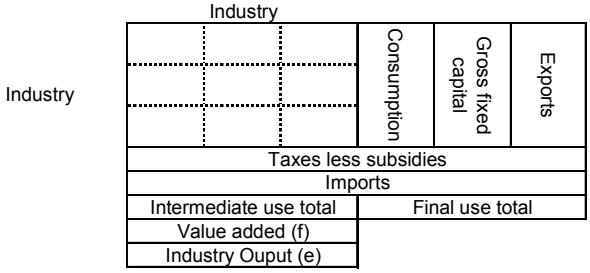

D. Use at basic prices (domestic)

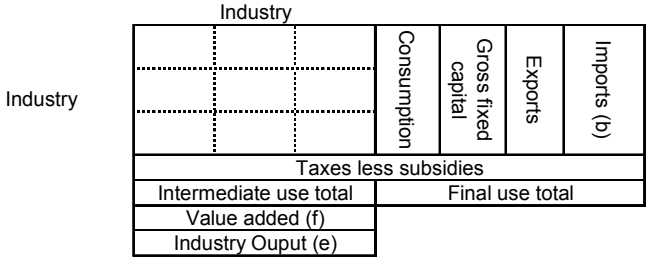

E. Symmetric/Use at basic prices (import)

F. Symmetric (domestic, ind x ind)

G. Symmetric (total, ind x ind)

7. Transformation to the harmonised industry-by-industry tables

Table 1 showed that the type of data received from each country varies considerably. Some countries have been able to provide symmetric I-O tables at basic prices at the required 48 industry level, whereas others have only been able to provide supply-use tables at purchaser's prices for example, using the industrial classification and industry detail usually presented in that country. Naturally this means that for many countries the data provided needs to be transformed or manipulated into the harmonised symmetric 48 industry-by-industry basis.

The process of transformation varies from country to country, depending on the information set supplied (see Box 1). Typically the process of transformation is as follows:

- *Supply and use tables at purchasers' prices – Convert use table to basic prices.*[10] Using supplementary information where available (for example, finance ministry sources for tax rates, such as VAT) or standard assumptions, we remove taxes and subsidies on products included in intermediate consumption and final demand and allocate these to a separate row. Again, using supplementary information where available, or standard assumptions, we remove trade margins (transport and distribution) from intermediate consumption and final demand cells and re-allocate these to the appropriate industry. Typically these standard assumptions assume that all consumers pay/receive the same rate of taxes/subsidies and pay the same rates of distribution margins, although these can be refined, depending on the information available. For example, if the tax column in the Supply matrix shows different taxes separately it is possible to ensure that VAT is only removed from those consumers that pay VAT (while taking into account that some industries, which differ across countries, cannot reclaim VAT). Similarly it is possible to ensure that all, or nearly all, retail margins (as opposed to wholesale) are removed from the HHFC column. For those countries that provide symmetric commodity-by-commodity tables at basic prices, however, it is preferable to use this information to derive the use table at basic prices by "reverse engineering" the transformation process as described below; a process used for Austria, France, Germany, Hungary, Italy, Portugal and Sweden.

- *Supply and use tables at basic prices (total economy only) – Convert use table into separate domestic and import use tables,* using either a straightforward proportionality assumption or, preferably, using information available on import use structures from earlier years (if these were not themselves derived using the proportionality assumption) constrained to the latest year totals using RAS techniques (for example, Canada 2000 using 1997 relationships), or by using the information provided by commodity-by-commodity import tables "reverse engineered" (an approach applied to Belgium and Turkey).

- *Supply and domestic use tables at basic prices – Convert supply and domestic use tables into symmetric industry-by-industry tables using the "fixed product sales structures" assumption (see Box 2).*

- *Symmetric industry-by-industry tables (domestic and total) – Aggregate the industries shown using national classification systems so that they are harmonised to the required 48 industry level (see Table 3).* For many countries it necessary to produce a concordance between the input-output, or supply-use, industries supplied by NSIs, their national classification systems and ISIC Rev. 3. For EU countries, which generally use the NACE classification (closely linked to ISIC Rev.3), this is fortunately a relatively simple task. However for non-EU countries separate concordance relationships between national classification systems and ISIC Rev. 3 have been used. As shown in Table 4 however, it is not always possible to assign each country's input-output industries or products to the harmonised input-output classification described in Table 3. In these circumstances the harmonised input-output table for any particular country includes, in some industries, all or part of another input-output group.

10. Many non-European countries typically produce their I-O tables on a producer price basis however the following six countries have been able to provide basic price tables despite their national convention: Japan, Korea, Brazil, Chinese Taipei, India and Indonesia.

Box 2. **Fixed product sales structures (industry technology) assumption**

For many countries symmetric industry-by-industry input-output tables have been derived from supply-use tables using the fixed product sales structures assumption – often referred to as the industry technology assumption (ITA), see also Section 8. The algebraic formulation of this method is described below:

The basic relationship that describes supply use tables can be shown as:

$$q=Bg+F \quad \text{(i)}$$

where, (q) is the vector of product outputs, (g) is the vector of industry outputs, ($B\hat{g}$) is the industry use matrix showing the purchases of goods and services by industries by product (rows) and industry (columns) and (F) the vector of final demand by product.

Let (M) be the matrix of supply of goods and services (rows) produced by industries (columns) so that we can define (D) as

$$D= M'\hat{q}^{-1} \quad \text{(ii)}$$

By multiplying both sides of equation (i) by (D), as shown in (ii) above, it follows that

$$Dq= DBg + DF = g \quad \text{(iii)}$$

that

$$(I-DB)g = F \quad \text{(iv)}$$

and

$$g= (I-DB)^{-1} F$$

$(I-DB)^{-1}$ reflecting the Leontief inverse.

It follows that the industry-by-industry use matrix = ($DB\hat{g}$) and (DF), the final demand by industry output. Note that this transformation to ($DB\hat{g}$) preserves, exactly, the value-added by industry relationships observed in the original industry use matrix (Bg).

For some countries, for example Korea, only commodity-by-commodity tables have been provided. Without additional information it is not possible to convert these tables into industry-by-industry tables and, as such, they remain on a commodity-by-commodity basis. For countries that provide commodity-by-commodity tables and a supply table but not a use table, for example Japan, it is possible to make a conversion to industry-by-industry tables. This process begins, in essence, by attempting to "reverse-engineer" the process typically used by NSIs to create the commodity-by-commodity tables, allowing the OECD to recreate the "original" use tables.[11] In practice this means working backwards with the commodity (or product) technology[12] assumption. Clearly this is not an ideal approach as the subsequent use table is converted to a symmetric industry-by-industry table using the "fixed industry sales structure"

11. Or rather the use table that is consistent with this approach, as some NSIs produce their commodity-by-commodity tables directly, that is they are not created by converting use tables.

12. See United Nations (1999).

(industry, as opposed to product, technology) assumption. However, in practice, the Leontief coefficients subsequently produced stand up to scrutiny. It might be preferable to reverse-engineer the process using the industry technology (or fixed product sales structures) assumption from the start but in some cases this leads to negative figures in the use table. As such, and partly because the method returns similar results where negatives do not occur, the standard approach is to reverse-engineer commodity-by-commodity tables using the product technology assumption.

Other adjustments are however needed in addition to the transformations referred to above. The following paragraphs describe the main adjustments made by the OECD Secretariat to arrive at harmonised tables.

FISIM adjustment

The allocation of financial intermediation services indirectly measured (FISIM) is treated differently across countries. For their most recent tables Australia, Japan, Canada, China, India, Indonesia, Chinese Taipei and the United States allocate imputed bank service charges directly to purchasing sectors, including, in some cases, households. EU countries have recently begun to adopt this process in their national accounts but the input-output tables received by the OECD do not yet reflect these changes – FISIM is instead shown as a separate column in their national input-output and supply-use tables; or as intermediate consumption of the finance industry (ISIC 65) with a corresponding deduction from gross operating surplus and value-added of the same industry.

For analytical purposes, and harmonisation, FISIM in the OECD database has been allocated separately to consuming industries as intermediate consumption of financial services, on the basis of each industry's share of total gross value-added for all countries (except those where FISIM has already been allocated), but not including the household and government sector. Value added in each industry is reduced by a corresponding amount. This treatment is consistent with the approach used in the 2002 edition of the I-O Database. SNA93, of course, recommends that FISIM should be allocated to all consumers; including final demand; however the information to do this is not readily available, in any case, doing so would lead to estimates of GDP and gross value-added that differed from those published by NSIs.

Disclosed cells and rounding errors

In some countries some data are suppressed by NSIs to preserve confidentiality. There are also some rounding errors which need to be corrected. Where this occurs, the OECD Secretariat has estimated these missing values and corrected for rounding errors using the bi-proportional algorithm (RAS). The bi-proportional adjustment was performed for example on the supply tables of the United Kingdom and the total, domestic and import tables of New Zealand.

c.i.f/f.o.b adjustments

For some countries specific adjustments are required to deal with valuation differences in imports. In the United States, France and Brazil for example imports of goods are valued at c.i.f prices (*i.e.* including cost, insurance and freight), as they should be, but with negative adjustments made to the imports of insurance and freight services (water transport only for France and transport more generally for Brazil) to correct for these services provided by resident producers (whose value is reflected in the c.i.f price of the imported product). Applying the proportionality method in this case to derive the import use matrix can lead to negative imports of these services however and so instead these negative values are removed from exports.

Summary of conversion methods for recent years

The following estimation methodologies have been applied for countries as follows:

- Symmetric industry-by-industry tables have been provided by the following 11 countries in the latest year: Australia, Canada, Denmark, Finland, Mexico, the Netherlands, New Zealand, Norway, Argentina, Brazil and Singapore.

- Supply and use tables have been provided by the following 21 countries, in the latest year, and the symmetric industry-by-industry tables have been estimated by the OECD using the fixed products sales structures assumption: *Austria, Belgium, Czech Republic, France, Germany, Greece, Hungary, Ireland, Italy, Poland, Portugal, Slovak Republic, Spain, Sweden, Switzerland, Turkey, United Kingdom, United States* (2000), *India* and *Israel*.

- Supply tables and symmetric product-by-product tables have been provided in the following two cases and so symmetric industry-by-industry tables have been estimated by reverse engineering the use table, as described above, before applying the industry technology assumption: *Japan* (2000) and *United States* (1995).

- Symmetric product-by-product tables, with no other information, have been provided in the latest year, unless otherwise stated, in the following 6 cases: *Korea*, *China*, *Chinese Taipei*, *Indonesia*, *Russia* and *Japan* (1995). These tables have not, therefore, been converted to industry-by-industry tables.

8. Industry-by-industry versus product-by-product tables

Given the widespread presentation of symmetric tables by many countries, especially within the European Union, it is perhaps important to explain why the OECD database is presented on an industry-by-industry format.

The first reason reflects the fact that the OECD Secretariat typically uses the database in conjunction with its many other datasets, for example the Structural Analysis Database, the Structural and Demographic Statistics Database, the International Energy Agencies (Emissions) Database, the Foreign Direct Investment Database, the Labour Force Survey Database, the Analytical Business Enterprise Research and Development Database, to name but a few; all of which are industry (with the exception of LFS data, which is easily convertible) datasets compatible with ISIC Rev. 3.

The second reason reflects a policy focus. Many of these analyses that use the OECD database are fundamentally concerned with the structure of industries and businesses across economies and the questions raised by these analyses can be better answered using industry-by-industry tables.

The third reason reflects statistical quality. In this context it is important to recognise that the data collected in producing supply-use tables, the key source for input-output tables in most countries, is based, with the exception of final demand components, almost entirely on business data (supply and intermediate consumption matrices). Business surveys typically ask for industrial output making little if any distinction between the intermediate inputs used in ancillary, secondary or by-product production. But this information is of course essential in producing commodity-by-commodity tables. Moreover commodity-by-commodity tables implicitly assume that primary products are produced using a homogenous production (technological) process (product technology assumption). Most studies of micro-level data however, whether looking at enterprises or establishments, suggest that this assumption is rarely met in

practice and that there is considerable heterogeneity in production processes of the same commodity (especially when commodities are presented at a 2, 3 or even 4 digit level).

In this context it is perhaps important to consider why product-by-product tables are commonly produced. It seems that this, at least in part, reflects a misunderstanding about the nature of the assumptions (methods) used to convert supply-use tables to symmetric industry-by-industry input-output tables.

Typically, symmetric industry-by-industry input-output tables are arrived at by converting supply-use tables using the industry-technology assumption. This (rather unfortunate as it turns out), description of the conversion method appears to be a main factor for the preference of commodity-by-commodity tables in some countries. "Unfortunate" because it suggests that the technology used in any particular industry is assumed to be the same, which most would accept as being unrealistic and certainly more stretching than the product technology assumption (even though, in many countries, the industry technology assumption is commonly used to derive commodity-by-commodity tables).

But as Thage 2005 shows this description of the conversion (industry-technology assumption) is inaccurate where industry-by-industry tables are concerned, and, is better described as *a fixed product sales structure* assumption. In other words the conversion merely assumes that the proportion of domestically produced commodity A bought by industry B from industry C is proportional to industry C's share of the total (domestic) economy production of commodity A. Put this way, it is clear that this is a far less demanding assumption than that implied by the equivalent, but differently named, "industry-technology" assumption. Moreover, in practice, the conversion to industry-by-industry tables best preserves the inter-industrial economic relationships that users are interested in. Most importantly it means that value-added and its components by industry are exactly the same as shown in supply-use tables (and so remain consistent with real data returns). This is not the case of course for commodity-by-commodity tables where, whatever the conversion methods used, value-added and its components are affected.

The fourth reason for the preference of industry-by-industry tables reflects the simplicity of the conversion techniques. Supply-use tables converted using the fixed product sales structure assumption return symmetric input-output tables without negatives. The same is also true for commodity-by-commodity tables converted using the industry technology, but from a philosophical perspective it seems incongruous to have a preference for commodity-by-commodity tables based on an assumption that industries have specific technologies.

ANNEX I: SUMMARY STATISTICS

This annex provides a simple example of comparative statistics derived using the latest version of the database: 2006 Edition.

Figure A1: Import structures

Simple ratios showing the shares of imports as a percent of total final demand, and intermediate consumption in particular, provide an indication of the degree of integration/interdependencies of economies in the global supply chain, although some care is needed in interpretation as flows of intermediate consumption of domestically produced goods are measured gross and because comparisons are not made at constant prices. Nevertheless these caveats notwithstanding the tables provide a strong indication that these interdependencies are growing, indeed since the 1990s these ratios have increased in 29 out of 31 countries, with, not surprisingly, a negative correlation between the economic size of a country and these ratios.

	Intermediate		Final demand	
	mid90s	early00s	mid90s	early00s
Australia	12.5%	13.0%	10.4%	10.9%
